$$W_{\mathrm{I}}/w_1 = (A_0B_2 - B_0A_2)/\Delta_2 \quad \ldots\ldots [12]$$

$$W_{\mathrm{II}}/w_2 = (B_0A_1 - A_0B_1)/\Delta_2 \quad \ldots\ldots [13]$$

where

$$\Delta_2 = A_1B_2 - B_1A_2 \quad \ldots\ldots [14]$$

Criticism of Method

Any one of the formulas [9], [10], and [11] for the three-bearing case and [12] and [13] for the two-bearing case will yield results with large errors if the positive terms are about equal to the negative terms.

Also the algebraic or other work or the apparatus involved in evaluating these equations by machine means is large so that it appears desirable to seek another approach with the hope of reducing the complication and increasing the accuracy.

The ideal condition in so far as accuracy is concerned would be (1) to have a trial weight located such that only pedestal A would be affected by it, (2) to have another trial weight located such that only pedestal B would be affected by it, and (3) to have still another trial weight located such that only pedestal C would be affected by it. If this were possible Equations [9], [10], and [11] would become

$$\frac{W_{\mathrm{I}}}{w_1} = \frac{A_0}{A_1} \quad \ldots\ldots [15]$$

$$\frac{W_{\mathrm{II}}}{w_2} = \frac{B_0}{B_2} \quad \ldots\ldots [16]$$

$$\frac{W_{\mathrm{III}}}{w_3} = \frac{C_0}{C_3} \quad \ldots\ldots [17]$$

There appears no simple way to find the location for single trial weights to fulfill this ideal since information on a large number of locations for trial weights can apparently only be found by making a large number of trial runs. But there will be *groups* of trial weights located only in the planes already selected which will have the desired property of affecting only one pedestal for each group.

Trial-Weight Groups Which Affect the Vibration at Single Locations Only

Let the weights r_1, r_2, and r_3 inserted at 1, 2, and 3, respectively, be of such relative magnitude and position that the vibration increment at A due to these weights is A_r and the vibration increment at B and C is zero. This is the equivalent of saying that if the weights r_1, r_2, and r_3 only are present the vibration at A would be A_r and that at B and C would be zero. Thus in Equations [9], [10], and [11] if W_{I}, W_{II}, and W_{III} are replaced by r_1, r_2, and r_3 then A_0 must be replaced by A_r and B_0 and C_0 set equal to zero; or

$$r_1/w_1 = A_r(B_2C_3 - B_3C_2)/\Delta \quad \ldots\ldots [18]$$

$$r_2/w_2 = -A_r(B_1C_3 - B_3C_1)/\Delta \quad \ldots\ldots [19]$$

$$r_3/w_3 = A_r(B_1C_2 - B_2C_1)/\Delta \quad \ldots\ldots [20]$$

Since r_1, r_2, and r_3 are as a group to be again considered as a trial weight, only the relation between them is necessary so that Equations [19] and [20] are each divided by [18] to obtain

$$r_3w_1/r_1w_2 = (B_3C_1 - B_1C_3)/(B_2C_3 - B_3C_2) \quad \ldots\ldots [21]$$

and

$$r_3w_1/w_3r_1 = (B_1C_2 - B_2C_1)/(B_2C_3 - B_3C_2) \quad \ldots\ldots [22]$$

Similarly, if s_1, s_2, and s_3 are weights which together cause a vibration increment only at B and this vibration is B_s then from Equations [9], [10], and [11] as before

$$s_1/w_1 = -B_s(A_2C_3 - A_3C_2)/\Delta \quad [23]$$

$$s_2/w_2 = +B_s(A_1C_3 - A_3C_1)/\Delta \quad [24]$$

$$s_3/w_3 = -B_s(A_1C_2 - A_2C_1)/\Delta \quad [25]$$

$$s_2w_1/s_1w_2 = (A_1C_3 - A_3C_1)/(A_3C_2 - A_2C_3) \quad [26]$$

$$s_3w_1/s_1w_3 = (-A_1C_2 + A_2C_1)/(-A_2C_3 + A_3C_2) \quad [27]$$

Finally if t_1, t_2, and t_3 are weights which together cause a vibration increment C_t at C and no vibration increment elsewhere, then corresponding to Equations [21], [22], [26], and [27]

$$t_2w_1/t_1w_2 = (A_3B_1 - A_1B_3)/(A_2B_3 - A_3B_2) \quad [28]$$

$$t_3w_1/t_1w_3 = (A_1B_2 - A_2B_1)/(A_2B_3 - A_3B_2) \quad [29]$$

In the two-bearing case replacing W_I and W_{II} with r_1 and r_2, respectively, in Equations [12] and [13] and replacing A_0 with A_r and B_0 with zero in a way similar to that used in the three-bearing case

$$r_1/w_1 = A_rB_2/\Delta_2, \qquad r_2/w_2 = -A_rB_1/\Delta_2 \quad [30]\ [31]$$

and

$$r_2w_1/r_1w_2 = -B_1/B_2 \quad [32]$$

Again replacing W_I and W_{II} with s_1 and s_2,

$$s_2w_1/s_1w_2 = -A_1/A_2 \quad [33]$$

Equations [21], [22], [26], [27], [28], and [29] for the three-bearing case and [32] and [33] for the two-bearing case give the proper relation of the trial weights in a group with respect to each other so that with one group of weights the vibration at only one location is affected.

After the vector relations in the trial groups are determined, all other data are discarded and trial runs are made with each group of weights considered as a single trial weight. When the r group is inserted the measured increment in vibration at A will correspond to a vector which will be denoted by A_r'. If the correction required of the r group is $-R$ then R is related to r the same as A_0 is related to A_r' so that

$$R/r = A_0/A_r' \quad [34]$$

Similarly, if $-S$ and $-T$ are corrections required of the s and t groups then the following corresponding relations obtain:

$$S/s = B_0/B_s' \quad \text{and} \quad T/t = C_0/C_t' \quad [35]\ [36]$$

Equations [34] and [35] also apply to the two-bearing case.

Summary of Group Method

1 Runs are made in the usual way, i.e., vibration readings are taken on the machine initially and then after each trial weight is inserted.

2 For bearing pedestal A, the relation between trial weights in a group such that only pedestal A will be affected is calculated. This calculation is then repeated for each of the other bearing pedestals. (Equations [21] to [29], inclusive, for the three-bearing case and Equations [32] and [33] for the two-bearing case.)

3 New runs are made with each trial-weight group and the vibration measured. These runs should show the intended result of vibration increments at only one pedestal for a given group of trial weights.

4 On the basis of these measurements the required magnitude and phase of each group are calculated from Equations [34], [35], and [36].

Discussion of Group Method

Since the assumptions on which unbalance-correction determinations depend only crudely apply, the consideration of errors is an important aspect of the problem of balancing. In most cases the greater the complication of the calculation process used between experimental measurements, the greater will be the error introduced by the calculation process. It appears, therefore, important to keep the number of mathematical operations between tests a minimum. Note that in Equations [21], [22], [26], [27], [28], and [29] for the three-bearing case the number of products plus the number of quotients is twenty four and that the number of additions plus the number of subtractions is nine, whereas in the original equations, [9], [10], and [11], the number of products plus the number of quotients is fifty one and the number of additions plus the number of subtractions is twenty. Equations [32] and [33] for the two-bearing case contain only two quotients, whereas in the original equations, [12] and [13], the number of products plus the number of quotients is eight and the number of additions plus the number of subtractions is three.

The calculation of the trial-weight-group relations does not complete the calculation or the determination as the calculation to which it is compared does, but the calculation of the trial-weight-group relations is all of the calculation required between experimental measurements so that the comparison is fair as a rough indication of the errors introduced by the calculation.

In many cases due to errors, even if they are minimized, the balance is not satisfactory after the first set of computed corrections is introduced. In fact balancing is usually a series of reductions in vibration rather than the complete elimination of vibration with a single determination. If the trial-weight-group relations are found to experimentally check in the group trial, then the second series of corrections can be made very simply by the reapplication of Equations [34], [35], and [36] where A_0 is taken to correspond to the remnant vibration at A after the first set of corrections has been applied. B_0 and C_0 (in the three-bearing case only) are also taken to correspond to the remnant vibration after the addition of the first set of corrections. This is a simpler process than the repeat calculation with the conventional method. It has the further advantage that each group of correction weights has a simple physical significance so that it is easier to follow the correction process. In fact the group method reduces multiplane balancing to the equivalent of single-plane balancing.

It may be that there is enough similarity between many machines so that the group-relation calculations are necessary only in a few typical cases. At any rate, a given group can be checked experimentally by an operator who does not have sufficient training to make the calculation in the first place and even if the group does not show exactly the property of affecting one location at a time it will likely come closer to it than the use of a single correction weight at a time. If it does, the process of successively using the group will converge where the single-weight process may not.

PART II—BALANCING WITH SELECTED CORRECTION LOCATIONS

For some rotors, especially those of irregular shapes, the balancing problem is different from the usual rotor-balancing problem in that the corrections are conveniently made in completely selected locations instead of in the ordinary way in which transverse planes are selected, but the angular position of the correction is left for determination.

For the case of a two-bearing rotor, if completely selected locations for corrections are to be used, four will be required if either addition or subtraction of weight can be made at each

location. In the general two-bearing case the four correction locations may be in four different transverse planes and four different axial planes. In the case of multicrank internal-combustion-engine crankshafts the corrections are usually made in four different transverse planes but they can ordinarily be confined to two axial planes.

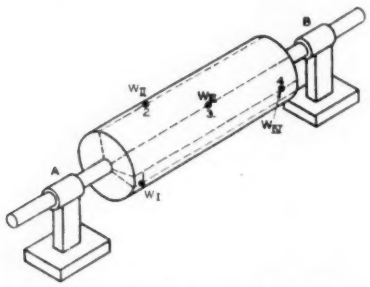

FIG. 2 DIAGRAM OF UNBALANCE COMPONENTS

To consider the general case first, refer to Fig. 2. The unbalance components at the general locations 1, 2, 3, and 4 are W_{I}, W_{II}, W_{III}, and W_{IV}, respectively.[6] The two bearing pedestals or other locations at which vibration is to be measured are A and B.

With a notation similar to that in part I,

$$\left.\begin{aligned} A_1(W_{\text{I}}/w_1) &= A_{\text{I}}; \quad A_2(W_{\text{II}}/w_2) = A_{\text{II}} \\ A_3(W_{\text{III}}/w_3) &= A_{\text{III}}; \quad A_4(W_{\text{IV}}/w_4) = A_{\text{IV}} \end{aligned}\right\} \quad [37]$$

$$A_0 = A_{\text{I}} + A_{\text{II}} + A_{\text{III}} + A_{\text{IV}} \quad [38]$$

$$\left.\begin{aligned} A_0 &= A_1\frac{W_{\text{I}}}{w_1} + A_2\frac{W_{\text{II}}}{w_2} + A_3\frac{W_{\text{III}}}{w_3} + A_4\frac{W_{\text{IV}}}{w_4} \\ B_0 &= B_1\frac{W_{\text{I}}}{w_1} + B_2\frac{W_{\text{II}}}{w_2} + B_3\frac{W_{\text{III}}}{w_3} + B_4\frac{W_{\text{IV}}}{w_4} \end{aligned}\right\} \quad [39]$$

where A_1 is the vector corresponding to the vibration at A due to the trial weight w_1 at location 1. A_{I} is the vector corresponding to the vibration at A due to the unbalance W_{I} only, which is completely known in position but unknown in amount. W_{I}/w_1 is a vector of zero angle and is the result sought. A_0 is the vector corresponding to the initially measured vibration, that is, with W_{I}, W_{II}, W_{III}, and W_{IV} present only. All the A's and B's are known in Equation [39]. Splitting the A and B vectors into their zero-degree and ninety-degree components and equating the zero-degree terms and the ninety-degree terms in Equations [39], four equations result

$$\left.\begin{aligned} \mathbf{A}_0 &= \mathbf{A}_1\frac{W_{\text{I}}}{w_1} + \mathbf{A}_2\frac{W_{\text{II}}}{w_2} + \mathbf{A}_3\frac{W_{\text{III}}}{w_3} + \mathbf{A}_4\frac{W_{\text{IV}}}{w_4} \\ \mathbf{a}_0 &= \mathbf{a}_1\frac{W_{\text{I}}}{w_1} + \mathbf{a}_2\frac{W_{\text{II}}}{w_2} + \mathbf{a}_3\frac{W_{\text{III}}}{w_3} + \mathbf{a}_4\frac{W_{\text{IV}}}{w_4} \\ \mathbf{B}_0 &= \mathbf{B}_1\frac{W_{\text{I}}}{w_1} + \mathbf{B}_2\frac{W_{\text{II}}}{w_2} + \mathbf{B}_3\frac{W_{\text{III}}}{w_3} + \mathbf{B}_4\frac{W_{\text{IV}}}{w_4} \\ \mathbf{b}_0 &= \mathbf{b}_1\frac{W_{\text{I}}}{w_1} + \mathbf{b}_2\frac{W_{\text{II}}}{w_2} + \mathbf{b}_3\frac{W_{\text{III}}}{w_3} + \mathbf{b}_4\frac{W_{\text{IV}}}{w_4} \end{aligned}\right\} \quad [40]$$

in which $\mathbf{A}$ and $\mathbf{B}$ indicate zero-degree terms and $\mathbf{a}$ and $\mathbf{b}$ indicate ninety-degree terms.

Solving Equations [40]

$$\frac{W_{\text{I}}}{w_1} = \frac{\begin{vmatrix} \mathbf{A}_0 & \mathbf{A}_2 & \mathbf{A}_3 & \mathbf{A}_4 \\ \mathbf{a}_0 & \mathbf{a}_2 & \mathbf{a}_3 & \mathbf{a}_4 \\ \mathbf{B}_0 & \mathbf{B}_2 & \mathbf{B}_3 & \mathbf{B}_4 \\ \mathbf{b}_0 & \mathbf{b}_2 & \mathbf{b}_3 & \mathbf{b}_4 \end{vmatrix}}{\Delta_3} \quad [41]$$

$$\frac{W_{\text{II}}}{w_2} = \frac{\begin{vmatrix} \mathbf{A}_1 & \mathbf{A}_0 & \mathbf{A}_3 & \mathbf{A}_4 \\ \mathbf{a}_1 & \mathbf{a}_0 & \mathbf{a}_3 & \mathbf{a}_4 \\ \mathbf{B}_1 & \mathbf{B}_0 & \mathbf{B}_3 & \mathbf{B}_4 \\ \mathbf{b}_1 & \mathbf{b}_0 & \mathbf{b}_3 & \mathbf{b}_4 \end{vmatrix}}{\Delta_3} \quad [42]$$

$$\frac{W_{\text{III}}}{w_3} = \frac{\begin{vmatrix} \mathbf{A}_1 & \mathbf{A}_2 & \mathbf{A}_0 & \mathbf{A}_3 \\ \mathbf{a}_1 & \mathbf{a}_2 & \mathbf{a}_0 & \mathbf{a}_3 \\ \mathbf{B}_1 & \mathbf{B}_2 & \mathbf{B}_0 & \mathbf{B}_3 \\ \mathbf{b}_1 & \mathbf{b}_2 & \mathbf{b}_0 & \mathbf{b}_3 \end{vmatrix}}{\Delta_3} \quad [43]$$

$$\frac{W_{\text{IV}}}{w_4} = \frac{\begin{vmatrix} \mathbf{A}_1 & \mathbf{A}_2 & \mathbf{A}_3 & \mathbf{A}_0 \\ \mathbf{a}_1 & \mathbf{a}_2 & \mathbf{a}_3 & \mathbf{a}_0 \\ \mathbf{B}_1 & \mathbf{B}_2 & \mathbf{B}_3 & \mathbf{B}_0 \\ \mathbf{b}_1 & \mathbf{b}_2 & \mathbf{b}_3 & \mathbf{b}_0 \end{vmatrix}}{\Delta_3} \quad [44]$$

$$\Delta_3 = \begin{vmatrix} \mathbf{A}_1 & \mathbf{A}_2 & \mathbf{A}_3 & \mathbf{A}_4 \\ \mathbf{a}_1 & \mathbf{a}_2 & \mathbf{a}_3 & \mathbf{a}_4 \\ \mathbf{B}_1 & \mathbf{B}_2 & \mathbf{B}_3 & \mathbf{B}_4 \\ \mathbf{b}_1 & \mathbf{b}_2 & \mathbf{b}_3 & \mathbf{b}_4 \end{vmatrix} \quad [45]$$

CRANKSHAFT BALANCING

The problem of balancing multicrank-engine crankshafts is a special case of the more general problem of balancing with selected correction locations just treated.[6] As illustrated in Fig. 3, two of the corrections can usually be placed in one axial plane or phase and two in another. This simplification makes the mathematical solution less involved than that of the more general case

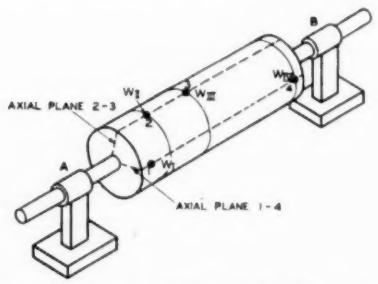

FIG. 3 DIAGRAM FOR CRANKSHAFT BALANCING

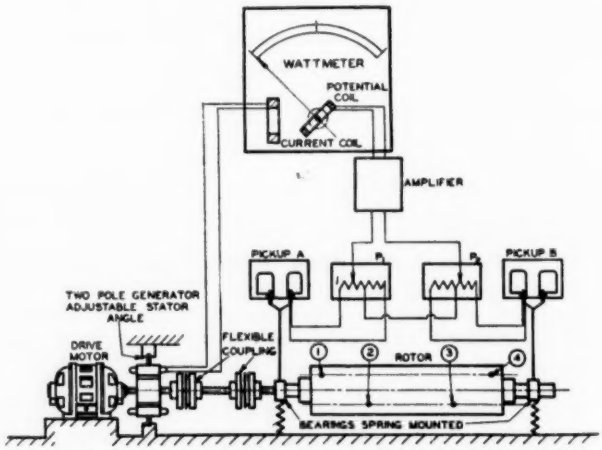

FIG. 4 ARRANGEMENT FOR READING THE UNBALANCE AT A GIVEN LOCATION

[6] If the rotor has different moments of inertia about the two principal inertia axes perpendicular to the rotational axis the analysis may not apply.

as given in Equations [41] to [45], inclusive, but still the mathematical solution is not practical since large numbers of shafts must be balanced. It appears, therefore, necessary to turn to machine means of obtaining the solution.

Description of Machine for Balancing. Fig. 4 shows a schematic diagram and Fig. 5 is a photograph of a commercial crankshaft-balancing machine. The circuit of Fig. 4 will indicate the unbalance component at one location at a time so that in the actual machine four such circuits are required with each setup for one unbalance location. Fig. 3 may be referred to to clarify the unbalance-correction position.

The rotor is mounted in very flexibly supported bearings so that the component of motion at one bearing due to one unbalance component will be either in phase or out of phase with the unbalance component. The motions of the bearings are used to actuate vibration pickups A and B so that voltages proportional to and in phase with the respective motions are produced. These voltages are divided by the potentiometers P_1 and P_2 and placed in series in such proportion that the resulting voltage is independent of any unbalance placed in one transverse plane. The settings of the potentiometers which will give a resultant change in voltage of zero for a weight added in the transverse plane of 4 will be called "setting 4," the settings of the potentiometers which will give zero resultant change in voltage for a weight added in the transverse plane of 3 will be called "setting 3," and so on. The resultant voltage in any case is amplified and placed on the potential coil of a wattmeter. The current coil of the wattmeter is energized by means of the two-pole generator turning with the rotor shaft.

The reading of the wattmeter, of course, depends on the phase relation between the current in the potential coil and the current in the current coil of the instrument. This phase relation may be adjusted by the manual rotation of the generator stator. In particular, the reading due to any unbalance in the axial plane

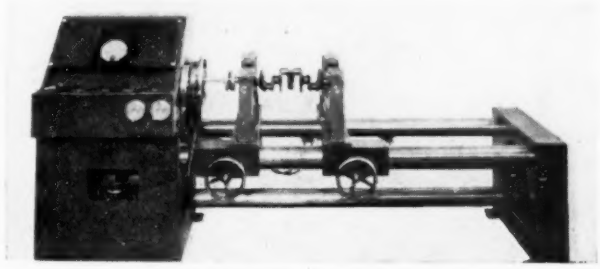

Fig. 5 Machine for Balancing Crankshafts

of 1 and 4 may be made zero by adjustment of the generator stator's angular position. If this adjustment is made and used in combination with a potentiometer setting 3, the deflection of the wattmeter must be due to unbalance at 2 only, so that calibration of this deflection is all that is necessary to make it a direct indicator of the unbalance correction required at 2 irrespective of what correction may be required at 1, 3, and 4.

Similarly if it is desired to read the unbalance at 1, the generator stator is adjusted so that unbalances in the plane of 2 and 3 do not register on the wattmeter and setting 4 on the potentiometers is used. The adjustments to read 3 and 4 correspond.

In short the indication of the unbalance component at a given location is obtained by using two elements. First, there is a measuring arrangement which can be adjusted so as not to indicate unbalances at a given phase.[7] This device eliminates from indication two of the four component unbalances. Second, a voltage-combining arrangement is used which eliminates the indication of a third unbalance component.[8] Thus the indication depends on only one of the four component unbalances.

It is of interest to note that the machine method corresponds to the mathematical method of solving a series of equations. The variables which are not sought are first eliminated and then the variable which is sought is evaluated.

PART III—CENTER-OF-PERCUSSION BALANCING[9]

For a rotor carried in a flexibly mounted frame, as in Fig. 6 or for the similar case of Fig. 7, a vibration reading taken at the proper location can be directly interpreted in terms of the unbalance corrections required in the planes 1 and 2.

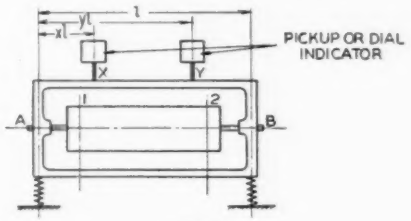

Fig. 6

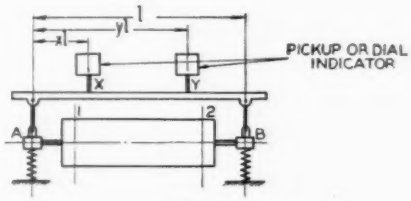

Fig. 7

Figs. 6 and 7 Diagrams for Center-of-Percussion Balancing

Let the motion perpendicular to the rotor axis at any point X along the frame (either Fig. 6 or Fig. 7) be X which is

$$X = A(1 - x) + Bx \quad [46]$$

where x is the ratio of the distance between X and A, to the distance l between A and B. Similarly the motion Y at another point will be

$$Y = A(1 - y) + By \quad [47]$$

where y is the ratio of the distance between Y and A, to the distance l.

The object is to choose x and y such that the vibration X_0 at X will be a measure of the unbalance component W_I at 1 and the vibration Y_0 at Y will be a measure of the unbalance W_{II} at 2.

Considering X and Y as stations similar to A and B and using the same subscript notation as in part I, an equation similar to [12] may be written

$$\frac{W_1}{w_1} = \frac{X_0Y_2 - Y_0X_2}{X_1Y_2 - Y_1X_2} = \frac{Y_0(X_2/Y_2) - X_0}{Y_1(X_2/Y_2) - X_1} \quad [48]$$

If X_2 could be made zero by proper selection of x then Equation [48] would become

$$W_1/w_1 = X_0/X_1 \quad [49]$$

[7] The wattmeter is not the only phase-sensitive device. Another example is a commutator running off the shaft of the rotor to be balanced.

[8] The voltage-combining arrangement may be replaced by a mechanical system.

[9] This method has been in use since about August 15, 1936, in Westinghouse service shops. It is so closely related to center-of-percussion theory that is doubtless very old, although no prior use has come to the author's attention.

Similarly, if Y_1 could be made zero

$$W_{II}/w_2 = Y_0/Y_2 \quad [50]$$

which are the results sought. Thus, the proper x and y might be obtained from Equations [46] and [57] by setting X_2 and Y_1 equal to zero thus:

$$0 = A_2(1 - x) + B_2x \quad [51]$$

$$0 = A_1(1 - y) + B_1y \quad [52]$$

or

$$x = A_2/(A_2 - B_2) \quad [53]$$

and

$$y = A_1/(A_1 - B_1) \quad [54]$$

Note that unless A_2 and B_2 are vectors of the same angle, and A_1 and B_1 are vectors of the same angle, x and y are not simple ratios as defined but vectors, so that, X_2 and Y_1 cannot be made zero and Equations [49] and [50] do not apply. However, with the condition of a flexible support imposed A_2 and B_2 will be vectors of the same angle provided the flexibility is high and the damping small since the rotor assembly would then be effectively free in space. Likewise, A_1 and B_1 will have the same angle and the method is applicable.

The point X as defined by Equation [53] is, of course, the node or center of oscillation for a force (of unbalance) at 2, and 2 is the center of percussion with respect to the point X. Y and 1 are similarly related. For simplicity w_1 and w_2 may be placed at zero angle, then X_0 and Y_0 will have the same angle as W_I and W_{II}, respectively.

Equations [49] and [50] may be used for the calibration of the readings.

Sometimes one of the calculated pickup locations may fall outside of the convenient range. This difficulty can be avoided either by (*a*) selecting a different correction combination, such as using an unbalance couple instead of single unbalance or by (*b*) using the two pickups in series instead of individually. In the latter case one pickup location may be selected and the other determined in a way similar to that described.

Tables of Moments and Deflections for a Rectangular Plate Fixed on All Edges and Carrying a Uniformly Distributed Load

By THOMAS H. EVANS,[1] CHARLOTTESVILLE, VA.

The problem of the clamped rectangular plate with a uniform load was solved by Hencky in 1913 and independently by Boobnoff in 1914. The former calculated values only for the case of a square plate. In 1937, Wojtaszak, using Hencky's method, calculated several other cases. In this paper the maximum moments and deflections for all side ratios between 1.0 and 2.0, by intervals of 0.1, are determined following Hencky's procedure. Growing out of the necessity for solving eight groups of simultaneous equations in twelve unknowns a short cut on the usual trial and error process of solution was developed.

THE PROBLEM of a rectangular plate clamped on four sides and carrying a uniformly distributed load is of great importance to the profession, but is one for which few numerical values for moment and deflection have been determined. For this reason the writer has calculated values of the maximum edge moments, center moments, and center deflections for various ratios b/a of the sides. Values omitted from the table, or otherwise noted, have been worked out by other investigators. Since the results at infinity are so little different from those at $b/a = 2.0$ the latter is taken as the upper limit.

The solution is obtained by combining the known solution for a simply supported plate under a uniform load with that of a plate bent by moments distributed along the pairs of opposite sides. It will be shown that by combining these two solutions we can finally satisfy all the requirements at the clamped edges.

The notation used in this paper is as follows:

- a = length of plate in x direction
- b = length of plate in y direction
- h = thickness of plate
- q = intensity of uniform load
- $D = \dfrac{Eh^3}{12(1-\nu^2)}$ = flexural rigidity of plate
- E = Young's modulus for the material
- ν = Poisson's ratio (taken equal to 0.3 in this paper)
- M = bending moment per unit length of plate
- w = deflection at any point
- $r = b/a$
- E_m and F_m are constants occurring in the expressions for moment and deflection
- m = 1, 3, 5, 7, ... ∞
- i = 1, 3, 5, 7, ... ∞
- n = 1, 3, 5, 7, ... ∞
- $\alpha = \dfrac{m\pi b}{2a}$, or deflection coefficient
- $\beta = \dfrac{m\pi a}{2b}$, or moment coefficient
- $K = -\dfrac{4qa^2}{\pi^3}$

[1] Department of Engineering, University of Virginia.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

For convenience in handling the relationships obtained, axes as shown in Fig. 1 are used, where the x- and y-axes are parallel to the short and long sides, respectively. In the case of a plate

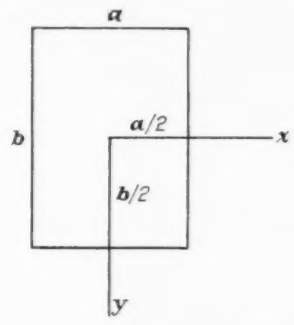

FIG. 1

with the two long edges simply supported and a moment M_y applied on the other two, the deflection is given by

$$w = -\frac{a^2}{2\pi^2 D}\sum_{m=1,3,5}^{\infty}\frac{E_m \cos\dfrac{m\pi x}{a}(-1)^{\frac{m-1}{2}}}{m^2\cosh\alpha_m}\left[\frac{m\pi y}{a}\sinh\frac{m\pi y}{a}-\alpha_m\tanh\alpha_m\cosh\frac{m\pi y}{a}\right] \quad \ldots\ldots [1]$$

It is assumed that $(M_y)_{y=\pm b/2} = \sum_{m=1,3}^{\infty} E_m \cos\dfrac{m\pi x}{a}(-1)^{\frac{m-1}{2}}$

The first derivatives of Equation [1] give

$$\left(\frac{\partial w}{\partial y}\right)_{y=b/2} = -\frac{a}{2\pi D}\sum_{m=1,3}^{\infty}\frac{E_m\cos\dfrac{m\pi x}{a}(-1)^{\frac{m-1}{2}}}{m}\left(\tanh\alpha_m+\frac{\alpha_m}{\cosh^2\alpha_m}\right) \quad \ldots\ldots [2]$$

and

$$\left(\frac{\partial w}{\partial x}\right)_{x=a/2} = \frac{a}{2\pi D}\sum_{m=1,3}^{\infty}\frac{E_m}{m\cosh\alpha_m}\left(\frac{m\pi y}{a}\sinh\frac{m\pi y}{a}-\alpha_m\tanh\alpha_m\cosh\frac{m\pi y}{a}\right)$$

$$= -\frac{1}{4D}\sum_{m=1,3}^{\infty}\frac{E_m}{\cosh^2\alpha_m}\left(b\sinh\alpha_m\cosh\frac{m\pi y}{a}-2y\cosh\alpha_m\sinh\frac{m\pi y}{a}\right) \quad \ldots\ldots [3]$$

To aid in making the last summation the quantity in parentheses is developed into a series, which gives

$$\left(\frac{\partial w}{\partial x}\right)_{x = a/2} = -\frac{4b^2}{\pi^2 aD} \sum_{m = 1, 3}^{\infty} \frac{E_m}{m^3} \sum_{i = 1, 3}^{\infty} \frac{i \cos \frac{i\pi y}{b} (-1)^{\frac{i-1}{2}}}{\left(\frac{i^2}{m^2} + \frac{b^2}{a^2}\right)^2} \quad \ldots\ldots [3a]$$

Now if moments are applied to the long edges, i.e., applied parallel to the x-axis, relationships can be worked out by similar reasoning. If $(M_x)_{x = \pm a/2}$

$$= \sum_{m = 1, 3}^{\infty} F_m \cos \frac{m\pi y}{b} (-1)^{\frac{m-1}{2}}$$

then

$$w = -\frac{b^2}{2\pi^2 D} \sum_{m = 1, 3}^{\infty} \frac{F_m \cos \frac{m\pi y}{b} (-1)^{\frac{m-1}{2}}}{m^2 \cosh \beta_m} \left(\frac{m\pi x}{b} \sinh \frac{m\pi x}{b} - \beta_m \tanh \beta_m \cosh \frac{m\pi x}{b}\right) \quad \ldots\ldots [4]$$

From which

$$\left(\frac{\partial w}{\partial x}\right)_{x = a/2} = -\frac{b}{2\pi D} \sum_{m = 1, 3}^{\infty} \frac{F_m \cos \frac{m\pi y}{b} (-1)^{\frac{m-1}{2}}}{m} \left(\tanh \beta_m + \frac{\beta_m}{\cosh^2 \beta_m}\right) \quad \ldots\ldots [5]$$

and

$$\left(\frac{\partial w}{\partial y}\right)_{y = b/2} = -\frac{4a^2}{\pi^2 bD} \sum_{m = 1, 3}^{\infty} \frac{F_m}{m^3} \sum_{i = 1, 3}^{\infty} \frac{i \cos \frac{i\pi x}{a} (-1)^{\frac{i-1}{2}}}{\left(\frac{i^2}{m^2} + \frac{a^2}{b^2}\right)^2} \quad \ldots\ldots [6]$$

The known solution for a uniformly loaded plate with simply supported edges is

$$w = \frac{4qa^4}{D\pi^5} \sum_{m = 1, 3}^{\infty} \left[\frac{1}{m^5} - \frac{(2 + \alpha_m \tanh \alpha_m)}{2m^5 \cosh \alpha_m} \cosh \frac{m\pi y}{a} + \frac{\frac{m\pi y}{a} \sinh \frac{m\pi y}{a}}{2m^5 \cosh \alpha_m}\right] \cos \frac{m\pi x}{a} (-1)^{\frac{m-1}{2}} \quad \ldots [7]$$

from which

$$\left(\frac{\partial w}{\partial y}\right)_{y = b/2} = \frac{2qa^3}{D\pi^4} \sum_{m = 1, 3}^{\infty} \frac{\cos \frac{m\pi x}{a} (-1)^{\frac{m-1}{2}}}{m^4} \left(\frac{\alpha_m}{\cosh^2 \alpha_m} - \tanh \alpha_m\right) \quad \ldots\ldots [8]$$

$$\left(\frac{\partial w}{\partial x}\right)_{x = a/2} = \frac{2qb^3}{D\pi^4} \sum_{m = 1, 3}^{\infty} \frac{(-1)^{\frac{m-1}{2}}}{m^4} \cos \frac{m\pi y}{b} \left(\frac{\beta_m}{\cosh^2 \beta_m} - \tanh \beta_m\right) \quad \ldots\ldots [9]$$

At $x = \pm a/2$ the summation of all $\partial w/\partial x$ terms should equal zero if the condition to be fulfilled is a fully clamped edge. Thus the sum of Equations [3a], [5], and [9] should equal zero. For like terms in these series the equality still holds; so if $m = i = n$, there results

$$\frac{F_n}{n}\left(\tanh \beta_n + \frac{\beta_n}{\cosh^2 \beta_n}\right) + \frac{8bn}{\pi a} \sum_{m = 1, 3}^{\infty} \frac{E_m}{m^3 \left(\frac{n^2}{m^2} + \frac{b^2}{a^2}\right)^2} = \frac{4qb^2}{\pi^3 n^4}\left(\frac{\beta_n}{\cosh^2 \beta_n} - \tanh \beta_n\right) \quad \ldots\ldots [10]$$

which provides one relationship for determining the constants $E_1, E_3, E_5, \ldots E_n$, and $F_1, F_3, F_5, \ldots F_n$. In the same manner another is found from the condition that $\partial w/\partial y$ must equal zero at the edges $y = \pm b/2$. That is

$$\frac{E_n}{n}\left(\tanh \alpha_n + \frac{\alpha_n}{\cosh^2 \alpha_n}\right) + \frac{8na}{\pi b} \sum_{m = 1, 3}^{\infty} \frac{F_m}{m^3 \left(\frac{n^2}{m^2} + \frac{a^2}{b^2}\right)^2} = \frac{4qa^2}{\pi^3 n^4}\left(\frac{\alpha_n}{\cosh^2 \alpha_n} - \tanh \alpha_n\right) \quad \ldots\ldots [11]$$

From Equations [10] and [11] as many terms and equations as thought necessary can be set up simultaneously. The form in which these equations for calculating the E and F coefficients were used is given in Equations [12] and [13]. For the values of r from 1.1 to 1.7 ten equations in ten unknowns were used; and for the remainder, twelve.

$$\left.\begin{aligned} &(n = 1)\ \frac{B_1 F_1 \pi}{1r} + \frac{8E_1}{(1 + r^2)^2} + \frac{24E_3}{(1 + 9r^2)^2} + \ldots \\ &\qquad + \frac{88E_{11}}{(1 + 121r^2)^2} = \frac{KB_1'\pi r}{1^4} \quad (a) \\ &\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \\ &(n = 11)\ \frac{B_{11}F_{11}\pi}{11r} + \frac{88E_1}{(121 + r^2)^2} + \ldots \\ &\qquad + \frac{968\,E_{11}}{(121 + 121r^2)^2} = \frac{KB_{11}'\pi r}{(11)^4} \quad (f) \end{aligned}\right\} \quad \ldots\ldots [12]$$

$$\left.\begin{aligned} &(n = 1)\ \frac{8F_1}{(1 + r^2)^2} + \frac{24F_3}{(9 + r^2)^2} + \ldots \\ &\qquad + \frac{88F_{11}}{(121 + r^2)^2} + \frac{E_1 A_1 \pi}{1r^3} = \frac{KA_1'\pi}{1^4 r^3} \quad (a) \\ &\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \\ &(n = 11)\ \frac{88F_1}{(1 + 121r^2)^2} + \ldots + \frac{968F_{11}}{(121 + 121r^2)^2} \\ &\qquad + \frac{E_{11}A_{11}\pi}{11r^3} = \frac{KA_{11}'\pi}{(11)^4 r^3} \quad (f) \end{aligned}\right\} \quad \ldots\ldots [13]$$

where $A_n = \tanh \alpha_n + \frac{\alpha_n}{\cosh^2 \alpha_n}$; $B_n = \tanh \beta_n + \frac{\beta_n}{\cosh^2 \beta_n}$

$$A_n' = \tanh \alpha_n - \frac{\alpha_n}{\cosh^2 \alpha_n}; \quad B_n' = \tanh \beta_n - \frac{\beta_n}{\cosh^2 \beta_n}$$

These equations could, of course, be solved by the trial-and-error method outlined by Wojtaszak.[2] Since, however, each

[2] "The Calculation of Maximum Deflection, Moment, and Shear for Uniformly Loaded Rectangular Plate With Clamped Edges," by I. A. Wojtaszak, JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 59, December, 1937, p. A-173.

different ratio of b/a required the solution of one such group (making eight groups in all) a method involving many less trials was finally developed. As pointed out by Wojtaszak each group took at least six trials to obtain accuracy to the required number of significant figures; where in the following outlined method only two or three at the most are needed. As a means toward this end the relationships between E_1 and E_3, E_5, E_7, and E_9 were worked out, as well as those between F_1 and F_3, F_5, F_7, and F_9, for the three cases at hand, namely, $r = 1.0$, 1.5, and 2.0. With these values a set of smooth curves was plotted as shown in Fig. 2, where the abscissa represent the b/a ratios from 1.0 to 2.0. From these curves one can obtain reliable values of any E in terms of E_1, or of any F in terms of F_1, for other b/a ratios. Thus it is seen that by not ignoring *any* factors in making the first approximation for such a group of simultaneous equations the first values obtained for the E's and F's are close to their true values. In most cases it was found that accuracy to four significant figures could be had after only two trials.

As an example of the use of this particular technic the detailed steps for the case of $b/a = 1.9$ are included. It should also be noted that in the final form of the equations used the coefficients for any row of F's in Equation [13] are the same as for the corresponding column of E's in Equation [12]. After reducing all the coefficients to decimal fractions in these two equations for the case $r = b/a = 1.9$ the values shown in the Example were obtained. Then by using the curves of Fig. 2, Equations [12a] and [13a] could be reduced to two simultaneous equations in two unknowns, F_1 and E_1. After obtaining these values F_3 was found from Equation [12b], again using all the factors containing E. The relationships were solved in order until all the F's had been calculated; and these in turn were substituted into Equation [13] until all the E's had been determined. With these first approximate values of the E's a second trial was made on the F's by again feeding in to Equation [12]. The process was

[a] Values obtained by other investigators.

stopped when it became apparent that the variation in the fifth significant figure would be less than five, since accuracy to four significant figures was all that was desired.

After obtaining these constants the values of the moments were calculated by substituting in the expressions for M_x and M_y. Total maximum deflection was calculated by adding algebraically the results from Eq. [1], [4], and [7] when $x = 0$ and $y = 0$. The maximum moment values occur at the middle of the sides, and that on the longer side is the greater of the two. In order to get precise values of the moments it would be necessary to take n out to 21 in some cases (22 equations in 22 unknowns). Another possibility was to take it out to some value, such as 11 used in this study, and from the trend of the E's to E_{11}, and of the F's to F_{11}, to get as many E and F values as desired by extrapolation. These trends were definite in all the cases studied by the writer and it is expected that the moment values given in Table 1 are not in error by as much as 0.1 per cent, which is well within any practical limits. The maximum error involved by using only terms up to $n = 11$ was less than 0.8 per cent.

The writer wishes to express gratitude to Prof. Stephen Timoshenko for suggesting this work. The relationships used to start solution of this problem were developed during lectures given by Professor Timoshenko at the University of Michigan. It is understood that this general method of approach was first suggested by H. Hencky in 1913.

Friction Coefficients for the Compressible Flow of Steam

By JOSEPH H. KEENAN,[1] CAMBRIDGE, MASS.

The effect of friction on the flow of compressible fluids in pipes of uniform cross-sectional area was investigated analytically by Grashof[2] and Zeuner[3] who arrived at a relationship between velocity and friction coefficient for ideal gases. Stodola[4] showed that "the curves of Fanno permit a general graphical treatment for any law of friction." Frössel[5] presented the first extensive measurements of friction coefficients for air flow through a smooth tube with velocities above and below the velocity of sound. His measured coefficients for compressible flow were in excellent agreement at corresponding Reynolds' numbers with coefficients measured for incompressible flow. Egli[6] expressed in dimensionless form the equations for flow of an ideal gas through a channel, and used them to deduce friction coefficients from measurements of flow through channels varying in width from 0.0025 in. to 0.010 in.

In this paper are presented some experiments by Lang[7] on friction in a commercial 1-in. pipe for steam flow at velocities up to the velocity of sound, and some auxiliary experiments by Benson[8] on a similar pipe with liquid water. In an Appendix the analysis of flow of a compressible fluid in a passage of uniform cross section is restated without introducing difficult concepts, such as "work of friction" or "heat of friction." It is elaborated to include cases in which heat flow is appreciable.

Steam Test Apparatus

THE ARRANGEMENT of the test apparatus is shown in Fig. 1. Fluid was supplied to a standard 1-in. steel pipe whose inside diameter averaged 1.05 in. This pipe comprised three long pieces which were joined by couplings, and a short length at each end, which was joined to the longer pieces by unions. Care was exercised to make each pair of lengths concentric where they joined. The entrance to the test pipe was a rounded entrance brass nozzle, details of which are shown in Fig. 2. The nozzle was fed in turn by a 4-in. pipe. The pressure measurements, which largely determined the friction coefficients of Table III and Fig. 9, were made at taps labeled p_1 and p_4 in Fig. 1. The first of these is in the nozzle wall, shown in Fig. 2, and the second near the downstream end of the test pipe. Both holes were carefully drilled and cleaned. Auxiliary pressure measurements were made at taps in the couplings joining the longer pieces of the test pipe. These taps were less perfect than the others, despite the fact that the pipe lengths were butted together in the coupling. Nevertheless, nothing in the test results indicates that these measurements were unsatisfactory. Pressure taps were provided also in the 4-in. supply pipe, p_0, where the velocity was always negligible, and in the 4-in. discharge pipe leading to the condenser p_5.

From each pressure tap a short length of horizontal tubing led to the middle of a large reservoir. A copper tube connected the bottom of the reservoir with one side of a mercury manometer. Before tests were begun the connecting tubing and reservoir were filled with water from below so as to sweep all air out of the system. In computing the measured pressures, allowance was made for the unbalanced water column.

The initial pressure p_0 was measured with a calibrated Bourdon-tube gage. All other pressures were measured by means of differential mercury manometers or, if the pressure changes exceeded the range of the manometers, by calibrated Bourdon-tube gages. Locations of the gages and manometers are shown in Fig. 1.

A copper-constantan thermocouple, shown as T_0 in Fig. 1, with its hot junction in the middle of the 4-in. approach pipe and a few inches before the nozzle, measured the initial temperature of the steam.

In order to determine heat loss from the bare pipe, its surface temperature was measured by means of copper-constantan thermocouples at the positions indicated as T_a, T_b, T_c, and T_d in Fig. 1. The thermocouple wires were soldered into grooves in the pipe wall.

All thermocouples used in these tests were calibrated against the temperature of equilibrium of liquid and vapor phases of water up to 400 F.

When the pipe was lagged to reduce heat loss, the surface temperature of the lagging was measured roughly by means of mercury-in-glass thermometers. However, heat loss from the lagged pipe proved to be so small that it could be ignored in calculating the friction coefficient.

The steam for the tests came from the Institute power plant, where it was generated at 200 lb per sq in. abs and 100 F superheat, through a long tunnel before entering the laboratory. After reaching the laboratory it passed through a well-insulated pipe which was trapped at frequent intervals to remove condensate. Upon reaching the nozzle of the test pipe it retained a superheat anywhere from 1 to 60 F, the amount depending upon the steam demand for other purposes. Despite the low initial

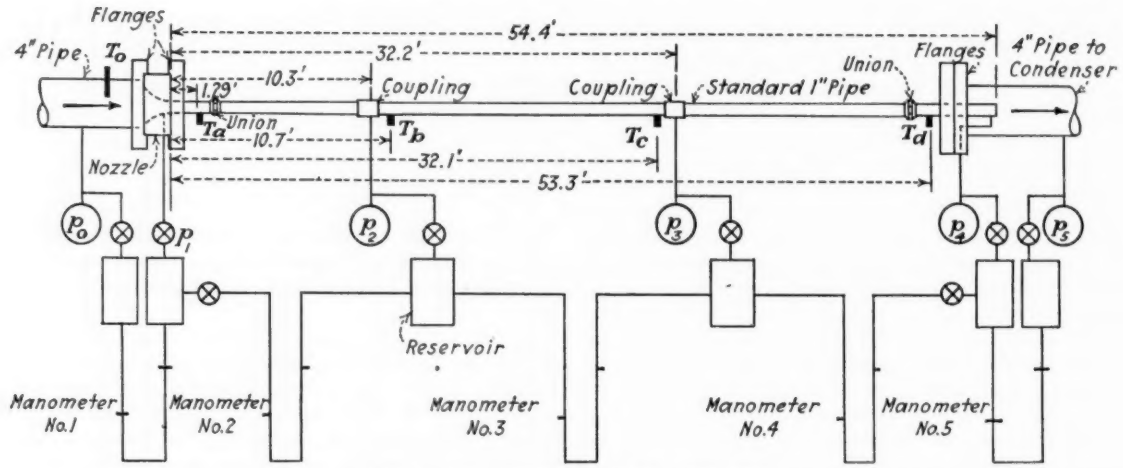

FIG. 1 ARRANGEMENT OF TEST APPARATUS

(The circles labeled P_0, p_2, etc., denote Bourdon-tube gages; T_0 denotes a thermocouple projecting into the stream; and T_a, T_b, T_c, T_d denote thermocouples soldered into grooves in the pipe wall.)

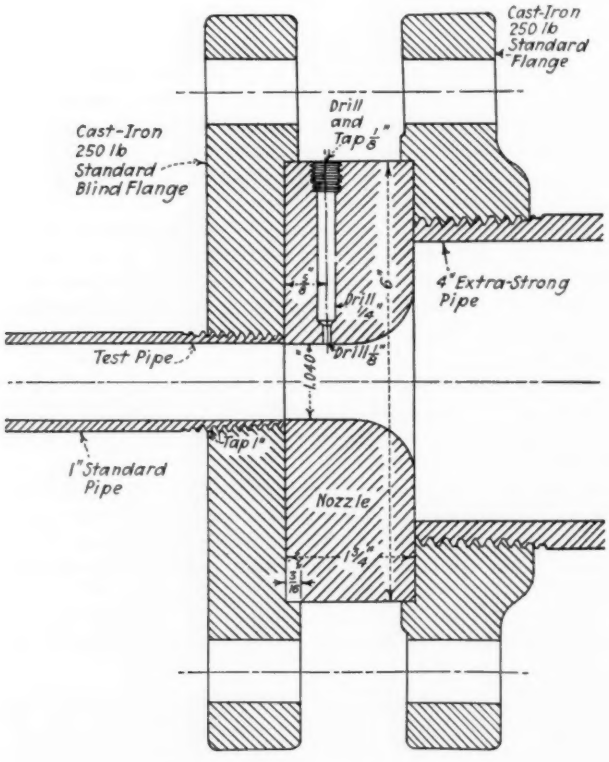

FIG. 2 INLET TO THE TEST PIPE

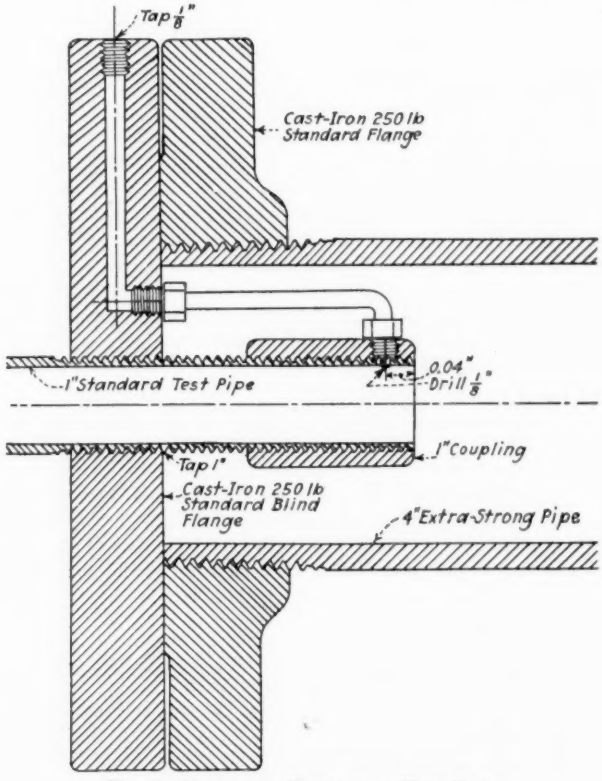

FIG. 3 DISCHARGE END OF THE TEST PIPE

(The final pressure tap is shown.)

superheat, which often was less than 20 F, the steam was usually slightly superheated where it left the nozzle and entered the test pipe.

Steam leaving the test pipe passed to a 4-in. pipe, as shown in Fig. 3, and then to a surface condenser. The condensate was weighed on calibrated platform scales.

WATER TEST APPARATUS

Essentially the same apparatus was used for the water tests as for the steam tests, but a few modifications were necessary. Since the water tests were made about eight months after the steam tests, the inside wall of the test pipe had become rough from corrosion. (In fact, some tests made on the corroded pipe gave friction coefficients about 15 per cent higher than those obtained from a new piece of pipe.) It was necessary, therefore, to install a new length of pipe in place of the middle length of the original test pipe. Because the pressure taps in the couplings were uncertain others were carefully made near each end of the new length. Only measurements made with these new taps were used in computing the friction coefficient.

Water from the city main was fed through a 2-in. pipe into a short length of 4-in. pipe preceding the nozzle. Straightening vanes in the 4-in. pipe insured against swirls which might have been introduced in some sharp bends in the preceding 2-in. pipe.

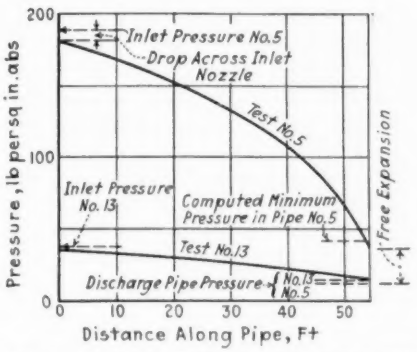

FIG. 4 PRESSURE DISTRIBUTION ALONG THE TEST PIPE

(The computed minimum pressure indicated for test 5 corresponds to single-phase expansion.)

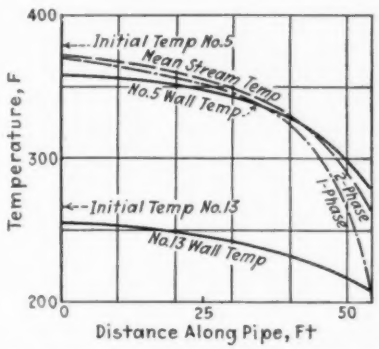

FIG. 5 TEMPERATURE DISTRIBUTION ALONG THE TEST PIPE

(The broken lines show computed values of the mean stream temperature.)

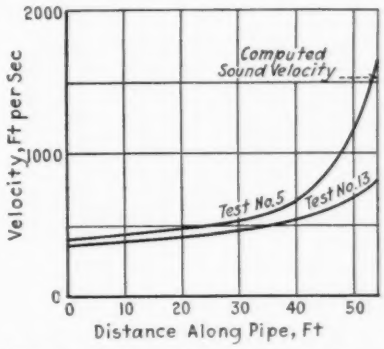

FIG. 6 VELOCITY DISTRIBUTION ALONG THE TEST PIPE

(The computed sound velocity indicated for test 5 corresponds to single-phase expansion.)

METHOD OF TESTING

In each test a control valve was set upstream from the apparatus to give the desired initial pressure or rate of flow. When a steady state was reached, readings were taken of all pressures and temperatures at definite intervals of time. The test was continued until adequate precision was attained in the measurement of flow.

RESULTS

The test results are presented in Tables 1, 2, and 3. The course of the pressure, temperature, and velocity along the length of the test pipe is shown in Figs. 4, 5, and 6, respectively, for two representative steam-flow tests, namely, tests 5 and 13. Test 5 is typical of seventeen tests in which the pressure in the exhaust pipe was below the pressure at the end of the test pipe and the rate of flow was therefore the maximum corresponding to the initial steam conditions. Test 13 is typical of the remaining six tests in which the steam left the test pipe at essentially the exhaust-pipe pressure, and the flow was therefore less than the maximum. The free expansion of the stream upon leaving the test pipe is indicated in Fig. 4 for test 5.

In Fig. 5 the outside wall temperature is compared with the mean steam temperature computed in two different ways: First, by assuming equilibrium between vapor and large water drops, for which the steam temperature would be the saturation temperature corresponding to the pressure; and second, by assuming that no liquid phase forms and that the vapor is in a supersaturated state. Evidence is presented in the Appendix that favors the second assumption. On either assumption the pipe-wall temperature is higher than the mean stream temperature for the last quarter of the length of the pipe. Since conduction of heat along the pipe must be small, it follows that near the pipe wall the fluid which has been slowed down by friction is at a temperature far above that of the main fluid stream.

It is shown in the Appendix that on the basis of certain assumptions it is possible to compute the lowest pressure and the highest velocity that can be attained in a pipe of uniform cross-sectional area, provided that the inlet velocity is less than the velocity of sound. The computed value of the lowest pressure (the pressure of maximum entropy) is shown for test 5 in Fig. 4, and the corresponding computed value of the highest velocity (the sound velocity) is shown in Fig. 6. It is evident that the expansion proceeds slightly beyond the computed limit. Frössel[8] found for air flow a deviation from the computed limit which is of the same sign and approximately the same magnitude as is indicated here for steam. He attributes the discrepancy to an assumption that underlies the computed value; namely, that the velocity is uniform across the pipe cross section.

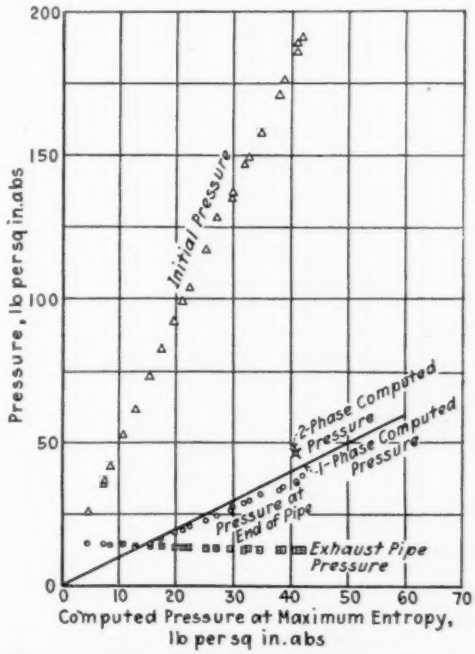

FIG. 7 RELATIONSHIP BETWEEN INLET PRESSURE, EXHAUST PRESSURE, AND PRESSURE AT THE END OF THE TEST PIPE

The relationship between the initial pressure, the final pressure in the test pipe and the exhaust-pipe pressure is shown in Fig. 7. The computed value of the minimum test-pipe pressure for single-phase expansion is shown by the solid line, which by virtue of the choice of abscissa is merely a line of equality between abscissa and ordinate. For comparison is shown a single computed value of the minimum pressure corresponding to two-phase equilibrium. The significance of this value is discussed in the Appendix.

In Fig. 8 the relationship between final test pipe pressure and flow is shown in dimensionless coordinates after the method employed by Frössel.[8] For comparison a part of the curve for frictionless flow is also shown. If continued it would reach $G/G_{crit} = 1$ at $p/p_0 = 0.542$.

Values of the friction coefficient, $R/{}^1/_{2\rho}V^2$, are given in Tables 1 and 3 and plotted against the mean Reynolds number[9] in Fig. 9.

For each of the tests with lagged pipe, Table 3 gives three friction coefficients, one for the first 32.2 ft of pipe length, one for the last 22.2 ft and one for the entire length. These values

[9] The method of computing the mean Reynolds number is described in the Appendix.

TABLE 1 RESULTS OF WATER TESTS

Test no.	Flow, lb per sec	Temperature, F	Pressure drop, lb per sq ft	Friction coefficient	Reynolds number $\times 10^{-4}$
1	8.168	39.5	2404.0	0.00522	11.350
2	7.017	39.5	1899.0	0.00572	9.740

7	0.809	39.3	35.0	0.00870	1.124
8	1.225	39.5	81.9	0.00810	1.701

NOTE: Cross-sectional area of pipe = 0.006 sq ft, and pipe length = 21.5 ft.

cent. Four tests are shown for which the pipe was lagged with a 1 in. thickness of 85 per cent magnesia. The effect of heat loss on the coefficients computed for these tests was less than $^1/_2$ per cent and was therefore ignored. It can be seen from Fig. 9 that the agreement between the coefficients corresponding to lagged pipe and unlagged pipe is excellent.

The solid line in Fig. 9 is the relationship between friction coefficient and Reynolds' number proposed by Nickuradse.[10] It represents with high precision the experimental data on smooth-

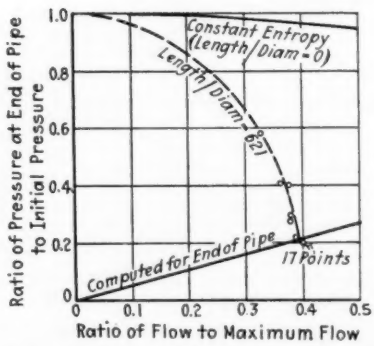

FIG. 8 RELATIONSHIP BETWEEN FLOW AND PRESSURE AT THE END OF THE TEST PIPE

(The computed minimum pressure at the end of the pipe for single-phase expansion is shown by the line sloping upward to the right. It meets the constant entropy curve at a pressure ratio of 0.542 and at a flow ratio of 1.0.)

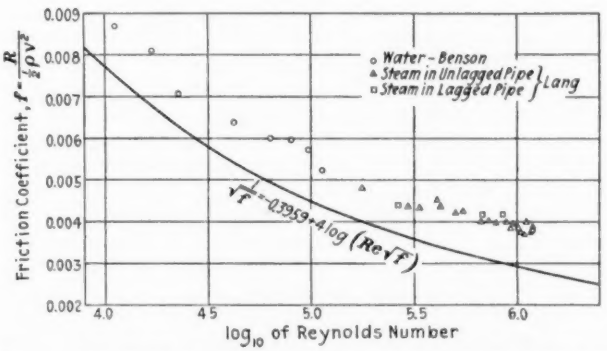

FIG. 9 MEASURED VALUES OF THE FRICTION COEFFICIENT FOR A 1-IN. COMMERCIAL PIPE

(The curve represents experimental data on smooth pipes.)

indicate that the friction coefficient is essentially independent of the velocity, provided that little change occurs in the Reynolds number. In Fig. 9 only the mean coefficient of friction for the entire pipe length is shown.

In the same figure are shown the friction coefficients obtained by Benson for water flow. The range of water pressure available did not permit tests with incompressible flow at as high Reynolds numbers as those for compressible flow. Nevertheless, the apparent continuity between the two sets of data offers evidence that the friction coefficient is substantially the same function of Reynolds' number for incompressible flow and for compressible flow up to the sound velocity.

Most of the steam tests were made with bare pipe, and for these an allowance was made for heat loss in the calculation of the friction coefficient. If no allowance had been made, the computed values of the coefficient would have been lower by 1 to 10 per

walled pipes up to a Reynolds number of 3.5×10^6. The experimental points of Fig. 9 for commercial 1-in. pipe show higher coefficients than are found for smooth pipes, but the character of the relationship between coefficient and Reynolds' number is much the same for the two cases. Because of the wide spread of values that have been published, no comparison is shown here with earlier data on commercial pipe. The present data are, however, consistent with various curves that have been selected on occasion to represent previously published values.[11]

The agreement between coefficients for compressible flow and incompressible flow shown in Fig. 9 is in accord with the results

[10] "Gesetzmässigkeiten der turbulenten Strömung in glatten Rohren," by J. Nickuradse, Forschungsheft No. 356, supplement of *Forschung auf dem Gebiete des Ingenieurwesens*, Berlin, September-October, 1932, p. 32.

[11] For example, see "Hydraulics," by G. E. Russel, Henry Holt & Co., New York, N. Y., 1934, fourth edition, wherein curve C on page 433 is in excellent agreement with the points of Fig. 9 of this paper.

[a] A systematic error is included in the friction coefficient by steps in those cases involving appreciable heat loss. The error is a result of an approximation to the Q-v relation which gives a satisfactory over-all coefficient, though it is inexact for the separate steps. Therefore, step values are given only for those tests in which heat loss was negligible.

of air-flow measurements made by Frössel.[5] In fact, the solid line of Fig. 9 is an excellent representation of a mean curve through all of Frössel's measurements both above and below the sound velocity.

Summary

It is found from tests with steam and liquid water on commercial 1-in. pipe that friction coefficients for compressible-fluid flow with velocities up to the velocity of sound and for incompressible-fluid flow are substantially the same function of the Reynolds number. The friction coefficient for commercial 1-in. pipe is higher for the same Reynolds number than that of smooth pipe by about 0.001.

The assumption that no moisture forms in a pipe if the steam

is initially slightly superheated is a satisfactory approximation to the truth. It seems to fit the observed phenomena better than the assumption of stable two-phase states.

The assumption that enthalpy is a linear function of the pressure-volume product facilitates analysis and computation, and is a satisfactory approximation to the true relationship for superheated and supersaturated vapor at low pressures.

The experimental results presented here on steam flow in commerical pipe are in qualitative agreement with those of Frössel[5] on air flow in smooth tubes.

Appendix

The Dynamic Equation for Flow in a Pipe of Constant Cross-Sectional Area

Consider an element of fluid which is bounded by two parallel planes transverse to the direction of flow and distant dx apart.

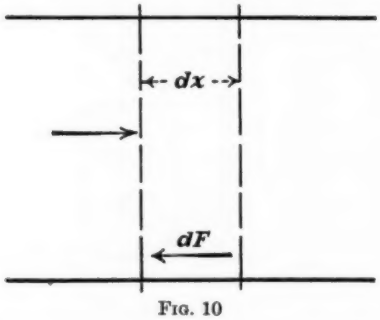

Fig. 10

The forces acting on this element may be classified as normal forces corresponding to hydrostatic pressures and shearing forces corresponding to wall friction. It can be shown that Newton's Second Law becomes for steady flow

$$-adp - dF = (w/g)dV, \qquad [1]$$

where a denotes the cross-sectional area of the passage, dp the increase in hydrostatic pressure of the fluid across distance dx, dF the wall friction force applied to the stream between the two planes, w the mass rate of flow, g the acceleration given to unit mass by unit force and dV the increase in the mean velocity of the stream across dx.

The wall-friction force dF may be expressed in terms of a friction coefficient which is commonly defined by the relation

$$f = R/{}^1\!/_2\rho V^2$$

where f denotes the friction coefficient, R the friction force per unit of wall surface, and ρ a mass density of the fluid which is otherwise $1/vg$. Then we may write

$$dF = R\pi D\,dx = fV^2\pi D dx/2vg$$

where D is the pipe diameter and dx is an element of length along the pipe. Substituting this expression for dF in Equation [1] dividing through by av and rearranging, we get

$$\frac{dp}{v} + \frac{G}{gv}dV + \frac{f}{2}\left(\frac{V}{v}\right)^2\frac{\pi D}{ag}dx = 0$$

where G is w/a. Since G for steady flow is constant along the length of the pipe and equal to V/v, the last equation may be written in the form

$$\frac{dp}{v} + \frac{G^2}{g}\frac{dv}{v} + \frac{2fG^2}{Dg}dx = 0 \qquad [2]$$

This is the dynamic equation of flow through a pipe. It may be used to determine the mean friction coefficient between two cross sections as follows:

Assume f to be constant between sections 1 and 2. Then Equation [2] integrates to the expression

$$\int_1^2 \frac{dp}{v} + \frac{G^2}{g}\ln\frac{v_2}{v_1} + \frac{2fG^2}{Dg}(x_2 - x_1) = 0 \qquad [3]$$

which may be solved for f. In an actual case f may be interpreted as the mean coefficient of friction. For a numerical solution it is necessary to know not only the dimensions of the pipe and the rate of fluid flow, but also the relationship between pressure and specific volume along the path of flow. In the incompressible case, which comprises the present tests with water, the specific volume is constant. Therefore, the first term becomes $(p_2 - p_1)/v$ and the second term vanishes. To get the pressure-volume relation for compressible flow we must turn to the first law of thermodynamics.

The Pressure-Volume Relationship

Let us first consider the adiabatic case, that is, the case in which heat flow to or from the fluid stream is negligible. Then from the first law of thermodynamics we know that for any section a along the pipe length the sum of the enthalpy and kinetic energy per unit mass of fluid crossing that section is constant and is equal to the enthalpy at a preceding section o where the cross-sectional area is very large and the kinetic energy is negligible: Thus

$$h + V^2/2g = h_o \qquad [4]$$

where h_o denotes the enthalpy at section o and the symbols without subscript denote quantities corresponding to section a. For V we may substitute Gv, so that Equation [4] becomes

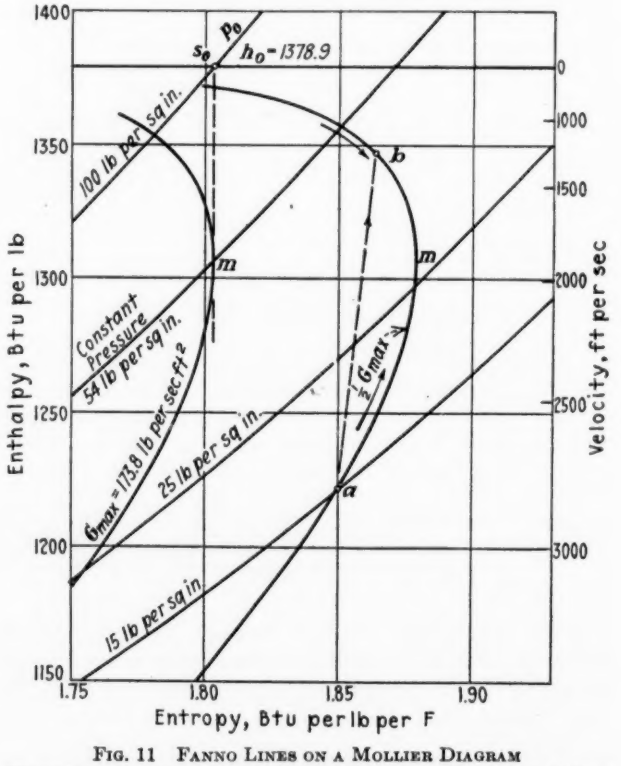

Fig. 11 Fanno Lines on a Mollier Diagram
(The velocity scale on the right holds good when the initial enthalpy is 1378.9 Btu per lb.)

$$h + G^2v^2/2g = h_o \quad \ldots\ldots [5]$$

where G is a constant in any steady-flow case for all sections having the same cross-sectional area. For a given state at section o, Equation [5] yields a series of relationships between h and v, each one of which corresponds to a value of G. In Fig. 11 two such relationships are drawn on an enthalpy-entropy diagram for one value of h_o. Stodola called them Fanno lines.[3]

Having determined by measurement the initial state o and the mass velocity G of a stream flowing through a pipe, we may determine by Equation [5] the h-v relationship and, with the steam tables as an aid, the p-v relationship corresponding. If two pressures, p_1 and p_2, at two sections 1 and 2 be now measured, it becomes possible to execute by graphic means or otherwise the integration indicated in the first term of Equation [3] and to compute the second term and the third term except for the single unknown f. Thus, the friction factor f is completely determined.

However, it would be convenient to have in place of the steam table an algebraic relationship between h, v, and p which represents the steam-table relations over the range in question with adequate precision and is yet simple in form. Such a relation is the equation

$$h = A + Bpv \quad \ldots\ldots [6]$$

in which A and B are constants. The constant A was chosen as 851.1 Btu per lb or 662,400 ft-lb per lb, and the constant B in its dimensionless form (corresponding to h in ft-lb per lb, p in lb per sq ft, and v in cu ft per lb) was chosen as 4.117. With these values, Equation [6] represents the relationship between h, p, and v for water vapor, superheated or supersaturated, to high precision for pressures under 100 lb per sq in.

Substituting Equation [6] into the Fanno-line Equation [5], we get

$$A + Bpv + \frac{G^2v^2}{2g} = h_o \quad \ldots\ldots [7]$$

which for given values of h_0 and G is a pure pressure-volume relation. Solving Equation [7] for p, differentiating and dividing through by v, we get for the first term of Equation [2]

$$\frac{dp}{v} = -\frac{G^2}{2gB}\frac{dv}{v} - \frac{h_o - A}{B}\frac{dv}{v^2}$$

Substituting this into Equation [3] and integrating between sections 1 and 2, we get

$$\frac{G^2}{g}\left(1 - \frac{1}{2B}\right)\ln\frac{v_2}{v_1} + \frac{h_o - A}{2B}\left(\frac{1}{v_2^2} - \frac{1}{v_1^2}\right) + \frac{2f\,G^2(x_2 - x_1)}{g\,D} = 0$$

or

$$= \frac{g\,D}{2G^2(x_2 - x_1)}\left[\frac{h_o - A}{2B}\left(\frac{1}{v_1^2} - \frac{1}{v_2^2}\right) - \frac{G^2}{g}\left(1 - \frac{1}{2B}\right)\ln\frac{v_2}{v_1}\right] \quad \ldots\ldots [8]$$

If measurements be made of the initial state, the rate of flow and the pressures at 1 and 2, the values of v_1 and v_2 can be found by solving the quadratic Equation [7]. Nothing further is needed to compute the friction factor from Equation [8].

Equation [8] is valid for any adiabatic case in which all states assumed by the steam are pure vapor states. However, in practically all of the tests reported here the Fanno line crosses the saturation line into the two-phase region before the discharge condition is reached. If moisture forms in large drops as soon as the saturation line is crossed, then Equation [6] does not hold good and Equation [8] is consequently invalid.

Evidence[12,13] has been accumulating recently that moisture does not form in a steadily flowing stream immediately upon passing the saturation line and almost never before reaching the end of the convergence in an expansion. Yellott and Holland[13] have shown experimentally that condensation begins in a nozzle only after the enthalpy has dropped some 60 Btu per lb below the saturation-line enthalpy at the same entropy. It has also been shown from Yellott's tests[14] that condensation does not immediately result in complete equilibrium with large drops of liquid.

Though the phenomena exhibited in Yellott's nozzles are not necessarily reproduced in flow through a pipe, it is reasonable to assume that within the supersaturation limit found by Yellott the state of steam in a pipe will more nearly approximate to a supersaturated vapor than to an equilibrium mixture of vapor and large drops. Since all states assumed by the steam in the present tests were within the supersaturation limit it was assumed that Equation [6] would hold good. Therefore, the friction coefficients presented here for the tests on insulated pipe (tests 20 to 23) were computed by means of Equation [8].

Friction With Heat Transfer

Enough heat transfer occurred from the unlagged pipe in tests 1 to 19 to justify an allowance for it in the computation of the friction coefficient. The dynamic Equation [2] is unaltered by heat transfer, because the Newtonian laws are independent of heat flow. The energy Equation [4], on the other hand, must be augmented by another term: Thus, for vapor states

$$A + Bpv + G^2v^2/2g = h_0 - Q \quad \ldots\ldots [9]$$

where Q is the heat transfer per unit mass of fluid between sections o and a. From this we find the first term of the dynamic equation to be

$$\frac{dp}{v} = -\frac{G^2}{2gB}\frac{dv}{v} - \frac{(h_o - A - Q)dv}{B \qquad v^2} - \frac{dQ}{Bv^2}$$

Substituting this in Equation [3], integrating and solving for f, we get

$$f = \frac{2ga}{G^2\pi D(x_2 - x_1)}\left[\frac{1}{B}\left(\int_1^2 \frac{dQ}{v^2} - \int_1^2 \frac{Q}{v^3}dv\right) - \frac{G^2}{g}\left(1 - \frac{1}{2B}\right)\ln\frac{v_2}{v_1} - \frac{h_o - A}{2B}\left(\frac{1}{v_2^2} - \frac{1}{v_1^2}\right)\right] \quad \ldots\ldots [10]$$

Values for v_1 and v_2 may be found from the measured quantities by solving the quadratic Equation [9].

Determination of heat transfer Q was based on the equations

$$dq = (H_c + H_r)\,\Delta t\,dA \quad \ldots\ldots [11][15]$$

$$H_c = 0.415(\Delta t/D)^{0.25} \quad \ldots\ldots [12][16]$$

and

$$H_r = 0.172e\,\frac{(T_1/100)^4 - (T_2/100)^4}{T_1 - T_2} \quad \ldots\ldots [13][17]$$

where q denotes the time rate of heat transfer; H_c and H_r denote respectively the coefficients of heat transmission by conduction and by radiation, Btu ft^{-2} F^{-1} hr^{-1}; Δt denotes the temperature difference between pipe surface and room, F; dA an element of pipe surface area, sq ft; D the outside pipe diameter, in.; T_1 the pipe surface temperature, F abs; T_2 the room temperature, F abs; and e the emissivity of the surface. Various approximations were permissible in the calculation of Q because of the small influence of heat transfer on the value of f.

The heat transfer for the entire pipe length comprised the loss from the bare flanges and nozzle block, and the loss from the test pipe. The former was found from an estimated value of $(H_c + H_r)$ of 2.8 Btu ft^{-2} hr^{-1} F^{-1}, and the latter was computed from Equations [11], [12], and [13] using 0.86 for the value of e. In most calculations the integral of Equation [11] was replaced by the approximate equation

$$q = (H_c + H_r)_m \Delta t_m A$$

in which subscript m denotes a mean value and A is the total pipe surface area.

The heat transfer was calculated for two finite lengths; namely, that between the inlet section o and section 3, and that between section 3 and the end of the pipe. Next, it was assumed that along the test pipe the relationship between v and Q could be adequately represented by an equation of the form

$$1/v^2 = m + nQ \quad [14]$$

where m and n are constants. The constant n was chosen to be the mean of the chord slopes between sections 1 and 3 and 1 and 4 on a $[(1/v^2) - Q]$ chart, while m was chosen so that the equation gave the correct relation at section 1. With the aid of Equation [14] it was possible to evaluate with adequate precision the two integrals in Equation [10] involving Q. The value of f could then be determined.

The State of Maximum Entropy

A stream of fluid can expand in adiabatic flow in a passage of uniform cross section until the state of maximum entropy is reached. Any further expansion must occur outside the passage. Since heat transfer is least near the discharge end of the test pipe in the tests under discussion, it is reasonable to assume that the state at the minimum discharge pressure for any initial condition is a state of maximum entropy.

For an infinitesimal change in pressure at the state of maximum entropy, we may write

$$ds = 0$$

or, for a pure substance in the absence of gravity, electricity, and capillarity

$$ds = (du + pdv)/T = 0 \quad [15]$$

where s denotes entropy, u internal energy, and v volume, each per unit mass, and p and T denote pressure and absolute temperature, respectively. By definition, the differential of enthalpy is given by the equation

$$dh = du + pdv + vdp$$

so that Equation [15] becomes

$$(dh - vdp)/T = 0$$

Thus, we have

$$dh = vdp \quad [16]$$

at the point of maximum entropy.

For the vapor phase we have already assumed that the h-p-v relationship is

$$h = A + Bpv \quad [6]$$

so that for any infinitesimal change in state the differential of h is given by

$$dh = B(pdv + vdp) \quad [17]$$

Combining Equations [16] and [17], we get

$$\frac{dp}{p} = -\frac{B}{B-1}\frac{dv}{v} \quad [18][18]$$

The Fanno-line equation for adiabatic flow near the end of the pipe is

$$h + G^2v^2/2g = h_o - Q$$

where Q is the heat loss between the initial section o and any section near the end of the pipe. Differentiation gives the equation

$$dh + \frac{G^2}{g} vdv = 0 \quad [19]$$

provided that heat loss near the end of the pipe is negligible. For the state of maximum entropy we get by Equations [16] and [19]

$$vdp + \frac{G^2}{g} vdv = 0$$

which can be transformed with the aid of Equation [18] to

$$-\frac{v}{p}\frac{dp}{dv} = \frac{G^2}{g}\frac{v}{p} = \frac{B}{B-1} \quad [20][19]$$

Solving the latter equation for v and substituting this and the hpv relationship into the Fanno-line equation, we get

$$A - p_s^2 \frac{B^2}{1-B}\frac{g}{G^2} + \frac{G^2}{2g} p_s^2 \left(\frac{B}{1-B}\right)^2 \left(\frac{g}{G^2}\right)^2 = h_o - Q$$

in which p_s denotes the pressure of maximum entropy. Solving for p_s we get

$$p_s = \frac{(B-1)G}{B}\sqrt{\left[\frac{2(h_o - A - Q)}{g(2B-1)}\right]} \quad [21]$$

The computed values of the pressure of maximum entropy

---

[18] For a finite change in state at constant entropy this equation integrates to the usual relation

$$pv^k = \text{constant}$$

where k denotes $B/(B-1)$. Therefore, the assumed hpv relation comprises the commonly assumed isentropic relation. For the value of B chosen here, namely, 4.117, the corresponding value of k is 1.321, which is in accord with values indicated for superheated and supersaturated states near saturation at low pressures by Fig. 8 of "Thermodynamic Properties of Steam," by J. H. Keenan and F. G. Keyes, John Wiley & Sons, Inc., New York, N. Y.

[19] From this equation it is evident directly that the velocity at the point of maximum entropy is the velocity of sound. For upon substituting V/v for G and solving for V, we get

$$V = \sqrt{(gpvk)}$$

where k is the isentropic exponent. This is the expression for the velocity of sound in a fluid of pressure p and volume v. See, for example, "Hydrodynamics," by Lamb.[20]

[20] Hydrodynamics by Horace Lamb, Cambridge University Press, 1930, p. 453.

shown in Figs. 4, 7, and 8 are found from Equation [21].[21]

Comparison of the Adopted Method of Calculation With a Method Based on Two-Phase Equilibrium

Regardless of the validity of Equation [6], it is entirely possible to find a h-v relationship corresponding to any test for which the intitial enthalpy, the rate of flow and the heat transfer are known. The Fanno-line equation, namely

$$h + G^2v^2/2g = h_o - Q$$

may be solved for h by assuming a value for v and estimating a corresponding value for Q. From the hv combination thus found a corresponding value of the pressure may be obtained from the steam table. With this value of pressure a second approximation to Q is possible, since Q is known as a function of distance by calculation, and pressure is known as a function of the same variable by measurement.

The resulting pressure-volume relation may be used in solving the dynamic Equation [3] for the friction coefficient. It is necessary, of course, to use a graphic integration or other approximate method to evaluate the term $\int dp/v$.

When this method was applied to test 5, the computed value of the friction coefficient was 0.00382 as compared with 0.00386 by the method in which single-phase states were assumed.

From the h-v relation for the two-phase calculation it is possible to find an approximation to the corresponding state of maximum entropy. For test 5 the pressure at this state was 46 lb per sq in. as compared with a computed single-phase value of 41.1 lb per sq in. and a measured value of 36.7 lb per sq in. The computed value for two-phase equilibrium exceeds the measured value by 25 per cent, and the computed value for single-phase states exceeds the measured value by 12 per cent. Frössel[5] found for air flow, in which there was no question of the appearance of a second phase, an excess of the computed value over the measured value of about 10 per cent. The agreement between Frössel's result and the single-phase computation lends weight to the probability that the liquid phase plays a negligible part in these experiments.

[21] Equation [8] can be solved for the rate of flow in terms of the friction coefficient and other quantities: Thus

$$G = \sqrt{\left\{\frac{\frac{h_o - A}{2B}\left(\frac{1}{v_1^2} - \frac{1}{v_2^2}\right)}{\left[\frac{1-\frac{1}{2B}}{g}\ln\frac{v_2}{v_1} + \frac{f\pi D(x_2 - x_1)}{2g\,a}\right]}\right\}}$$

To obtain the expression for the maximum rate of flow per unit area corresponding to any initial enthalpy we must substitute for v_2 the value corresponding to p_s. For this a combination of Equations [20] and [21] gives

$$v_s = \sqrt{\left[\frac{2g}{G^2}\left(\frac{h_o - A}{2B - 1}\right)\right]}$$

When this substitution has been made, the only quantity remaining in the expression for the maximum G which cannot be readily obtained from the measurements is v_1.

Now if we assume the flow through the entrance nozzle to be frictionless, v_1 becomes a function of G and the initial state; thus

$$G = \sqrt{\left\{2g\,\frac{P_0}{v_0}\,\frac{k}{k-1}\left(\frac{v_0}{v_1}\right)^2\left[1 - \left(\frac{v_0}{v_1}\right)^{k-1}\right]\right\}}$$

The maximum flow through a given pipe for a prescribed initial state will be found at the intersection of the two curves of G against v_1 corresponding to the two expressions for G here given.

In an actual case, this process of solution becomes a method of successive approximations; for f, which was at first assumed, is dependent on the Reynolds number which is in turn dependent on G.

The Mean Reynolds Number

The friction coefficient computed from the steam tests is a mean friction coefficient. It can be seen by comparing Equations [2] and [3] that its definition in terms of point values of the friction coefficient f is

$$\bar{f} = \frac{\int_1^2 f\,dx}{x_2 - x_1}$$

where $\bar{f}$ denotes the computed value, hitherto denoted by f.

Assume that over the range of Reynolds' number covered by any one test the relationship between point values of the friction coefficient and the Reynolds number is given by an equation of the kind

$$f = a\mathrm{Re}^n$$

where Re denotes Reynolds number and a and n are constants. Then, we may write for the mean friction coefficient

$$\bar{f} = \frac{a\int_1^2 \mathrm{Re}^n\,dx}{x_2 - x_1}$$

which is identical with the point value of the friction coefficient corresponding to a value of Re given by

$$\left(\frac{\int_1^2 \mathrm{Re}^n\,dx}{x_2 - x_1}\right)^{1/n}$$

This may be called the mean Reynolds number.

Careful calculations of a few instances indicate that the mean Reynolds number can be approximated within 2 per cent by a simpler calculation. It consists of fitting a quadratic equation of the form

$$\mathrm{Re} = ax^2 + bx + c$$

to the Re-x relation at 0 ft, 32.2 ft, and 54.4 ft from the nozzle throat and then calculating for this quadratic the mean Reynolds number defined by the equation

$$\overline{\mathrm{Re}} = \int_1^2 \mathrm{Re}\,dx/(x_2 - x_1)$$

The values of mean Reynolds number given in Table 3 correspond to this equation with the integral and difference taken over the entire length of the test pipe.

Sample Computations

Water Test 1. From Equation [3]

$$f = \frac{Dg(p_1 - p_2)}{2vG^2(x_2 - x_1)}$$

From data given in Table 1, the following values are determined: $D = 1.05$ in. $= 0.0875$ ft; $p_1 - p_2 = 2404$ lb per sq ft; $v = 0.01602$ cu ft per lb; $G = 8.168/0.006$ lb per sec per sq ft; and $x_2 - x_1 = 21.5$ ft. Then, $f = 0.00530$.

Steam Test 5. By Equation [10]

$$f = \frac{2ga}{G^2\pi D(x_2 - x_1)}\left\{\frac{1}{B}\left[\int_1^2 \frac{dQ}{v^2} - \int_1^2 \frac{Q}{v^3}\,dv\right] - \frac{G^2}{g} \times \left(1 - \frac{1}{2B}\right)\ln\frac{v_2}{v_1} - \frac{h_o - A}{2B}\left(\frac{1}{v_2^2} - \frac{1}{v_1^2}\right)\right\}$$

Let us compute the over-all value of the mean friction coefficient. Referring to Tables 2 and 3, we get $a = 0.006$ sq ft; $G = 163.19$ lb per sec per sq ft; $D = 0.0875$ ft; $(x_2 - x_1) = 54.4$ ft; $B = 4.117$; and $A = 662{,}400$ Btu per lb.

Using a step-by-step integration of the heat-loss Equation

[11], we get the values given in Table 3 for the heat loss between the initial section and sections at distances 0, 32.2, and 54.4 ft downstream from the test-pipe entrance. Substituting these values into the Fanno-line equation

$$A + Bpv + G^2v^2/2g = h_o - Q$$

along with measured values of the pressure for each of the three stations, we get a quadratic which can be solved for v. The three resulting values are given in Table 3. The first and third may be substituted for v_1 and v_2, respectively, in the expression for f.

To evaluate the two integrals involving Q, we first choose values of the constants in the equation

$$1/v^2 = m + nQ$$

after converting the values for Q into ft-lb per lb. The value of n for the length 0 to 32.2 ft proves to be -3.3079×10^{-5}, while that for the remaining length is -4.1971×10^{-5}. Selecting the mean value, or -3.7525×10^{-5}, we get for m the value 0.17654. From the v-Q relation we get

$$\frac{1}{B}\int_1^2 \left[\frac{dQ}{v^2} - \frac{Q}{v^3}\,dv\right] = \left\{-\frac{3}{4n}\left[\left(\frac{1}{v_1^2}\right)^2 - \left(\frac{1}{v_2^2}\right)^2\right] + \frac{m}{2n} \times \left(\frac{1}{v_1^2} - \frac{1}{v_2^2}\right)\right\}\frac{1}{B} = (514.8 - 355.4)/4.117 = 38.72 \text{ lb}^2 \text{ ft}^{-5}$$

Other quantities appearing in the expression for f are

$$\frac{G^2}{g}\left(1 - \frac{1}{2B}\right)\ln\frac{v_2}{v_1} = 1028.04 \text{ lb}^2 \text{ ft}^{-5}$$

$$\frac{h_o - A}{2B}\left(\frac{1}{v_2^2} - \frac{1}{v_1^2}\right) = 4971.16 \text{ lb}^2 \text{ ft}^{-5}$$

$$\frac{2g\,a}{G^2\pi D(x_2 - x_1)} = 0.9694 \times 10^{-6} \text{ ft}^5 \text{ lb}^{-2}$$

Then $f = 0.9694 \times 10^{-6}\,(38.72 - 1028.04 + 4971.16) = 0.003860$

The Determination of the Expansion Forces in Piping by Model Test

By HAROLD W. SEMAR,[1] PHILADELPHIA, PA.

The paper describes apparatus for testing models of piping installations to determine the forces set up in the full-size installation due to expansion. The method consists in fixing one end of the model in a slide which can be moved a measured amount, and measuring the forces at the other end by means of a fixture which holds that end rigidly in place and permits measurement of six forces in three coordinate planes, which are the equivalent of forces in coordinate directions plus moments in coordinate planes. The slide of the movable end is placed so that its direction of motion coincides with the direction of the pipe expansion.

A complete example is given showing the steps in determining the end reactions of an inlet pipe for a steam turbine.

IN THE DESIGN of piping, consideration must be given to the forces and stresses set up by expansion of the pipe and by movement of the end supports. In modern central-station power plants where the main steam lines carry steam at 1200 pounds pressure and 925 F, this problem is especially important.

The design of the piping system, therefore, requires a means of predicting the expansion stresses and forces so that sufficient flexibility can be provided with a minimum of bends and extra pipe length. Methods of calculating piping have been published[2,3,4] and are in general use at the present time. When the pipe lies in a single plane the calculation can be readily made, but when the pipe is three-dimensional the calculation is long and tedious.

An accurate solution of complicated piping systems can be made, however, by tests of a scale model. This method is now in use by the Westinghouse Electric & Manufacturing Company in checking the forces exerted on large steam turbines by the inlet and exhaust piping.

When a pipe expands with an increase in temperature, the forces exerted by the ends of the pipe are the same as those produced by freeing one end of the pipe, allowing it to expand, and then restoring the free end to its original position. The expansion forces can thus be duplicated by a displacement of one end of the pipe equal to the expansion but in the opposite direction. The problem is then one of load deflection and can be exactly described by a scale model.

The model test is essentially a scale model of the full-size pipe made of steel tubing and rigidly clamped at both ends, with provision for moving one end without rotation and for measuring the forces at the other end.

Fig. 1 is a photograph of the apparatus set up for making a model test. The movable end of the model is bolted to a tool slide mounted so that its direction of motion coincides with the direction of the pipe expansion. The fixed end of the pipe is held in a frame that enables the forces which are acting on the pipe to be measured. This frame is the feature of the test arrangement.

The reaction of the end of the pipe can be defined by a force in each of the three coordinate directions and a moment in each of the three coordinate planes. The three moments are present because the end of the pipe is restrained from rotation in any direction. The six coordinate forces and moments are shown in Fig. 2. Each of the three moments can be replaced by a couple, one force of which acts in a coordinate direction. For instance, in Fig. 3 the moment M_{zy} is replaced by two forces in opposite directions, of magnitude M_{zy}/b, and a distance b apart, one of which is in the direction of P_x. By similarly replacing the other two moments by couples, the six equivalent forces of Fig. 4

result. The six coordinate forces and moments are readily converted to the six equivalent forces by the relations

$$\left.\begin{aligned} R_x &= P_x - \frac{M_{xy}}{b} + \frac{M_{zz}}{b} & R_{xy} &= \frac{M_{xy}}{b} \\ R_y &= P_y & R_{yz} &= \frac{M_{yz}}{b} \\ R_z &= P_z + \frac{M_{yz}}{b} & R_{zz} &= \frac{M_{zz}}{b} \end{aligned}\right\} \quad \ldots\ldots [1]$$

which are evident in Fig. 3.

Conversely, if the equivalent forces of Fig. 4 are known the coordinate forces can be found by

$$\left.\begin{aligned} P_x &= R_x + R_{xy} - R_{zz} & M_{xy} &= b\,R_{xy} \\ P_y &= R_y & M_{yz} &= b\,R_{yz} \\ P_z &= R_z - R_{yz} & M_{zz} &= b\,R_{zz} \end{aligned}\right\} \quad \ldots\ldots [2]$$

The bracket which holds the fixed end of the pipe is supported so that each of the six equivalent forces can be measured. This bracket is shown in Fig. 5. It is held in place by twelve pins or struts which act in the positive and negative directions of the six equivalent forces. In Fig. 5, for instance, the forces R_x and $-R_x$ represent the location of one pair of pins. These pins are supported as shown in Fig. 6. Each pin rests on a button which in turn rests on a shoulder of a sleeve that is screwed into a solid frame. The sleeves are adjusted to allow about 0.002 in. movement of the bracket so that one pin transmits the force to the bracket while the other is slack. Actually, the pin corresponding to $+R_y$ was omitted to allow clamping the model, and the model must be mounted so that R_y remains negative during the test.

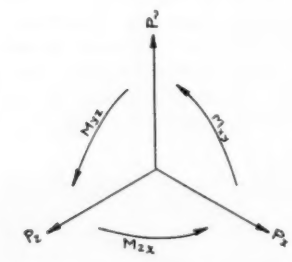

FIG. 2 COORDINATE FORCES

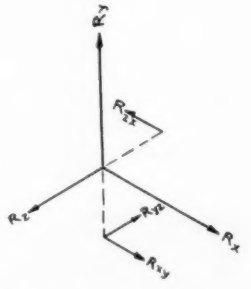

FIG. 4 EQUIVALENT FORCES

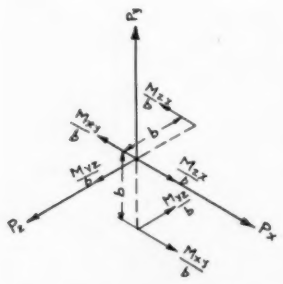

FIG. 3 MOMENTS REPLACED BY COUPLES

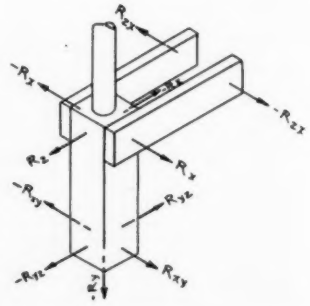

FIG. 5 BRACKET FOR HOLDING MODEL

The force transmitted to the bracket is then the force required to just lift the button from its seat. Measurement of this force is accomplished with the weighing instruments shown in Fig. 7. The instrument on the left is simply a dial indicator which bears on the button supporting the slack pin. It serves to show when the opposite button is moved, and to check the clearance between the pins. The instrument on the right contains a plunger and calibrated spring, and is screwed onto the sleeve supporting the tight pin. The plunger bears on the button with an increasing force as the instrument is screwed onto the sleeve, compressing the spring until the indicator on the opposite side shows that the button has been lifted. The indicator on the right measures the compression of the spring to determine the force acting. To measure $-R_y$, which has no pin opposite to show when the button is lifted, the weighing instrument is screwed over the sleeve in the same way. The point at which the button is just raised is determined by tapping the model. When the button lifts from its seat, the tapping is carried to the indicator of the weighing instrument. The six forces are noted for several positions of the movable end of the model. These are plotted against the linear movement of the pipe end, and the average slopes of these curves are taken as the model deflection constants, R_x, R_y, R_z, R_{xy}, R_{yz}, and R_{zz}, which are forces per unit deflection. The deflection is taken as positive in the direction opposite to that of the pipe expansion, and care must be taken of the signs of the model deflection constants.

If the model were exactly to scale and of the same material as the full-size pipe, the forces on the full-size pipe would simply equal the model forces divided by the scale of the model.

However, it is convenient to make the model only of standard sizes of steel tubing and to depart somewhat from a true scale model. The model forces can still be readily transferred to the full-size forces if the factor $\lambda = tR/r^2$ (where t = wall thickness, R = radius of pipe bend, and r = mean radius of pipe cross section), which is the index of the increased flexibility of the bends due to the flattening of the pipe section is kept the same. This can be done by selecting a standard size of steel tubing having approximately the same ratio of wall thickness to diameter and then taking a length scale to give the same value of λ. This condition will be met if the scale be taken as

where subscripts m and a denote, respectively, the model and full-size-pipe dimensions.

Then, for the same deflection the forces in the full-size pipe and the model will be in the ratio

$$\frac{\frac{E_a I_a}{R_a^3}}{\frac{E_m I_m}{R_m^3}} = \frac{E_a I_a}{E_m I_m} s^2 = K \quad \ldots\ldots\ldots\ldots\ldots [4]$$

and the moments in the ratio

$$\frac{E_a I_a}{E_m I_m} s^2 = \frac{K}{s} \quad \ldots\ldots\ldots\ldots\ldots [5]$$

where

K = model-to-pipe conversion factor
E_a = modulus of elasticity of actual pipe
I_a = moment of inertia of actual pipe section
E_m = modulus of elasticity of model
I_m = moment of inertia of model section
s = scale of model.

The actual forces and moments exerted by the full-size pipe are then

$$\left.\begin{aligned} P_x &= (R_x + R_{xy} - R_{zx})Ke \\ P_y &= R_y Ke \\ P_z &= (R_z - R_{yz})Ke \\ M_{xy} &= (b/s)R_{xy}Ke \\ M_{yz} &= (b/s)R_{yz}Ke \\ M_{zx} &= (b/s)R_{zx}Ke \end{aligned}\right\} \quad \ldots\ldots\ldots [6]$$

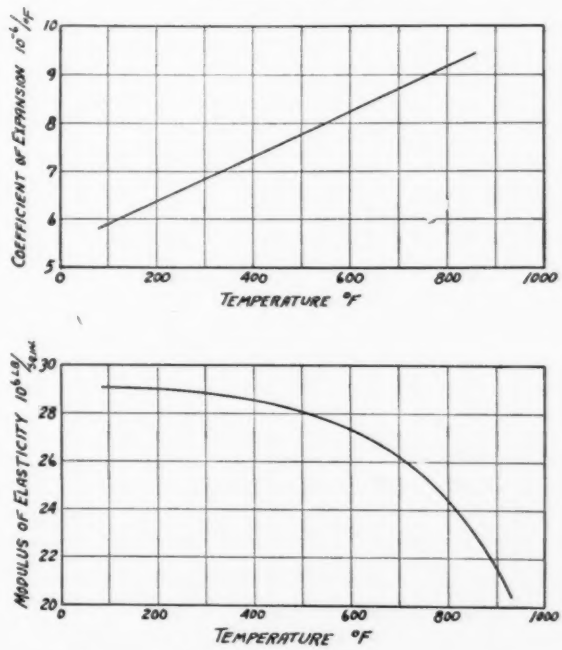

FIG. 10 MODULUS OF ELASTICITY AND COEFFICIENT OF EXPANSION FOR CARBON STEEL

where b is the moment arm of the model forces R_{xy}, R_{yz}, and R_{zx} as shown in Fig. 3 and e is the linear expansion or combination of expansion and end movement of the full-size pipe. It is the vector sum of the expansion and end movements in the coordinate directions.

A complete example is given in Figs. 8 and 9 which shows all the steps in determining the end reactions of an inlet pipe to a steam turbine. In this case, the movement of the end of the pipe due to expansion of the turbine is taken into account. No consideration is taken of cold springing of the pipe, since the forces are simply proportional to the expansion less the cold spring. Thus, if the pipe is cold-sprung 60 per cent of the expansion, the forces when the pipe is hot will be 40 per cent of those given.

As shown in Fig. 10 the modulus of elasticity of steel is affected by high temperatures and must be considered. Consequently, the forces when the pipe is cold will be 60 per cent of those given times the ratio of the moduli of elasticity cold and hot.

Branch systems are tested simply by using an additional slide for each additional branch.

By the method outlined, the expansion forces set up in steam piping can be reliably determined, with an error no greater than the experimental error in the measurement of the forces. Numerous and irregular bends and skew sections of pipe add only to the time required to construct the model and in no way complicate the test procedure.

Analysis of Effect of Wire Curvature on Allowable Stresses in Helical Springs

By A. M. WAHL,[1] EAST PITTSBURGH, PA.

The author suggests a method for determining the effect of wire or bar curvature on allowable stresses in helical springs, based on the endurance properties of the material. The method is based on the assumption, in agreement with available fatigue-test data, that stress-concentration effects produced by wire curvature may be neglected in calculating the static component of applied stress; also, it is assumed that the relation between the static- and variable-stress components at failure follows a linear law. On this basis, charts are given for determining maximum allowable stress as a function of spring index, ratio of minimum to maximum stress, and ratio between yield point and endurance limit. The effect of sensitivity of the material to stress concentration is taken into account by introducing a sensitivity-index q. Results calculated by means of the equations given show good agreement with results from tests of springs of different indexes. Some of the limitations of the method are discussed, and suggestions are made for future testing work.

AN ARTICLE[2] published in 1929 gave the results of strain measurements on helical springs, and indicated that the maximum stress in such springs may be much higher than that figured by using the conventional helical-spring formula. The difference is particularly pronounced for springs having small indexes, i.e., low ratios of coil diameter to wire diameter. This stress increase may be accounted for by (1) direct shear due to the axial load and (2) stress-concentration effects due to wire or bar curvature. On the basis of the strain measurements, reported in the 1929 paper,[2] an approximate formula was developed for calculating the maximum stress in such springs. The application of this formula involves the multiplication of the conventional formula for helical springs by a factor K which depends on the spring index.

The results which were computed by this theory were in close agreement for practical springs with an approximate formula given by Röver[3] in 1913, and also with a more exact formula developed later by Göhner who applied the theory of elasticity to the problem.[4] While it may be said that the problem of calculating the maximum stress in helical springs as affected by wire curvature has been solved[5] (assuming elastic conditions) the problem of predicting analytically the effect of these stresses on the actual fatigue strength of helical springs has received but little attention. There has, however, been a general opinion among spring engineers, based on experience, that the use of the factor K of Fig. 1 will result in too low values of the permissible working load. This view was confirmed to a certain extent by the results of a series of carefully made fatigue tests on small helical springs of different indexes carried out by Zimmerli[6] which showed that the limiting stress range in fatigue, when figured by using the K-factor, was higher for the springs of smaller indexes. Similar results were reported by Edgerton[7] in connection with the fatigue testing work being done on heavy helical springs by the A.S.M.E. Special Research Committee on Mechanical Springs. These tests will be discussed later.

An increase in the limiting stress range[8] with decrease in spring index may, in the author's opinion, be explained by the fact that

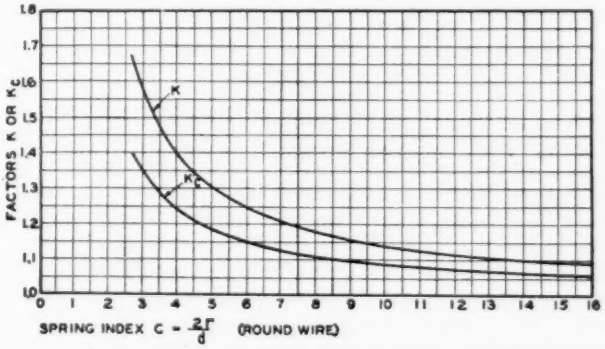

FIG. 1 CURVE FOR DETERMINING FACTORS K OR K_c FOR HELICAL TENSION OR COMPRESSION SPRINGS

(The factor K includes both the effects of curvature and direct shear; the factor K_c includes stress-concentration effects due principally to curvature.)

in helical springs the stresses as computed by the factor K are very much localized at the inside of the coil; for this reason the factor K may be considered to act in some degree as a stress-concentration factor. Fatigue tests[9] made in recent years on specimens having stress concentration indicate that the latter

may be neglected in computing the static component of the applied stress. In Fig. 2 are shown the results of some fatigue tests made on 0.7 per cent carbon-steel bars[10] in tension-compression. The full lines represent tests on bars without notches, the lower curve representing minimum and the upper curve maximum values of the limiting stress range. The dot-and-dash line represents the static or mean component of the applied stress, while the difference between this line and either the upper or lower curve represents the variable stress component. When the

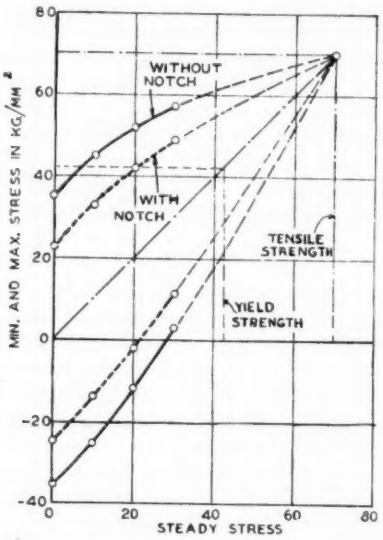

FIG. 2 NOTCH EFFECT IN FATIGUE STRESSING WITH INITIAL TENSION

(For 0.7 per cent carbon steel. According to tests by Schenck referred to in footnote 10.)

bars are notched, thus producing stress concentration, the endurance range is reduced as shown by the dashed lines on this figure, all stresses being figured in this case by neglecting the stress concentration due to the notch. It will be noted that the static component of stress as represented by the dot-and-dash line is practically unchanged by the presence of the notch; the effect of the notch is mainly to reduce the amount of variable stress which can be carried by the test piece, corresponding to some stress-concentration factor. Thus, in this case, it is seen that the static stress may be figured by neglecting stress-concentration effects while the latter must, however, be considered in calculating the variable stress.

Since practical helical springs are always under a combination of static and variable loading, if we neglect stress-concentration effects which are due to bar curvature the result is a higher permissible working stress (this is figured by using the K-factor of Fig. 1).

A further reason why the factor K cannot be directly applied in spring design lies in the fact that some materials, particularly in the smaller specimens, when tested in fatigue do not show the full stress-concentration effects predicted by theoretical methods (strain measurements, photoelastic tests, or mathematical analysis). This lack of sensitivity to stress concentration is a function of both wire or bar size and material,[11] the finer-grained high-strength alloy steels showing much higher sensitivity than the coarse-grained medium-carbon steels.

METHOD OF CALCULATION ASSUMING FULL SENSITIVITY TO STRESS CONCENTRATION

In accordance with the previous discussion, a method of calculation for helical springs is suggested. This method, which is similar to the general one proposed by Soderberg,[12] is based on the following assumptions: (1) Stress-concentration effects due principally to curvature in helical springs may be neglected in figuring the static component of the stress; (2) the relation between the values of static- and variable-stress components at failure follows a linear law; (3) the tensile and fatigue properties of the wire are the same in springs of different indexes, assuming the same size wire; (4) the effects of eccentricity of loading due to the end turns are neglected; (5) residual stresses produced by overstressing or surging the springs may be neglected. These factors will be more fully discussed later.

To determine the stress-concentration effect (due mainly to curvature) the stress multiplication factor K, shown in Fig. 1, is first split up into two parts, thus

$$K = K_s K_c \quad [1]$$

where K_s is a factor which takes into account the average stress produced by the direct shear due to the axial load, and K_c is a factor which takes into account the stress-concentration effect due mainly to curvature. Since the stresses due to direct shear are not localized, as is the case with those due to curvature, it is not believed that the factor K_s may be neglected in figuring the static component of stress. Assuming the shear stress due to the axial load as uniformly distributed over the cross section of the wire, the stress due to direct shear is[13]

$$s_s = \frac{16Pr}{\pi d^3}\frac{0.5}{c} \quad [2]$$

where the term $16Pr/\pi d^3$ is the stress figured by the conventional spring formula and c is the spring index $2r/d$. Thus

$$K_s = 1 + (0.5/c) \quad [3]$$

and from Equation [1]

$$K_c = \frac{K}{K_s} = \frac{K}{1 + (0.5/c)} \quad [4]$$

The factor K_s is shown in Fig. 1 as a function of the spring index c.

Referring to Fig. 3, the dashed line shows a typical experimental curve of failure for materials under a combination of static and variable stress. The ordinates represent values of variable stress which will just cause failure when superimposed on the static stresses shown by the abscissas. Assume that fatigue tests are made on a spring of large index ($c = \infty$) so that $K_c = 1$. Let s'_e denote the endurance limit in pulsating stress (zero to maximum) obtained on this spring. Then the point P on the diagram is determined, since for this case (pulsating stress) both the static- and variable-stress components are equal to $s'_e/2$. As an approximation, we replace the experimental curve by the straight line PA drawn to intersect the axis of abscissas at s_y, the yield point

[10] According to tests by Schenck; see "Federstähle" by Houdremont and Bennek, *Stahl und Eisen*, vol. 52, 1932, p. 660.

[13] All stresses considered in this analysis are torsion stresses.

of the material in torsion. This is done since in general no stress should exceed the yield point.[14]

To apply this diagram in actual design, assume that the spring is operating under a stress range from s_{min} to s_{max} in fatigue where these stresses are figured by using the factor K. Then the variable stress s_v is

$$s_v = \frac{s_{max} - s_{min}}{2} \quad [5]$$

and the static stress is

$$s_o = \frac{s_{max} + s_{min}}{2K_c} \quad [6]$$

The right side of the last equation is divided by K_c since this factor has already been used in figuring s_{max} and s_{min}; therefore, to neglect stress-concentration effects due to curvature, division

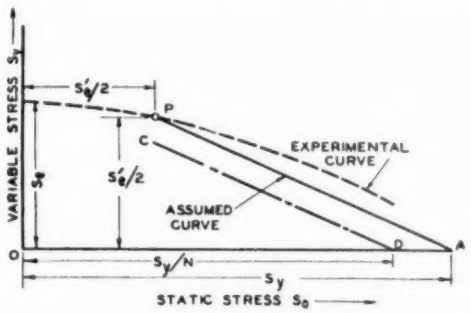

FIG. 3 APPLICATION OF STRAIGHT-LINE LAW TO HELICAL SPRINGS WHEN THE ENDURANCE LIMIT s'_e FOR PULSATING LOAD APPLICATIONS (ZERO TO MAXIMUM) AND THE YIELD STRESS s_y ARE KNOWN
(All stresses are torsion stresses.)

by K_c is necessary. The equation for the line PA, shown in Fig. 3, in terms of s_o and s_v is

$$\frac{s_o}{s_y} + \frac{s_v}{\frac{s'_e}{2}\left[\frac{s_y}{s_y - (s'_e/2)}\right]} = 1 \quad [7]$$

Substituting the values of s_v and s_o given by Equations [5] and [6] we find

$$s_{max} = \frac{2s_y}{\frac{1}{K_c}\left(1 + \frac{s_{min}}{s_{max}}\right) + \left(\frac{2s_y}{s'_e} - 1\right)\left(1 - \frac{s_{min}}{s_{max}}\right)} \quad [8]$$

This equation gives the maximum stress[15] s_{max} in terms of K_c, s_y, s_{min}/s_{max}, and s_y/s'_e and may be written

$$s_{max} = C_w s'_e \quad [9]$$

where C_w is a function of K_c, s_y, s_{min}/s_{max}, and s_y/s'_e. Thus

$$C_w = \frac{2s_y/s'_e}{\frac{1}{K_c}\left(1 + \frac{s_{min}}{s_{max}}\right) + \left(\frac{2s_y}{s'_e} - 1\right)\left(1 - \frac{s_{min}}{s_{max}}\right)} \quad [10]$$

Since K_c is a function of spring index c, values of C_w may be plotted in the form of charts for various spring indexes and various values of s_y/s'_e.

For design purposes we introduce a factor of safety N so that the working stress becomes

$$s_{w_{max}} = C_w(s'_e/N) \quad [11]$$

It may be shown that this amounts to assuming a curve CD, shown in Fig. 3, parallel to the line PA and intersecting the axis of abscissas at a distance s_y/N from O.

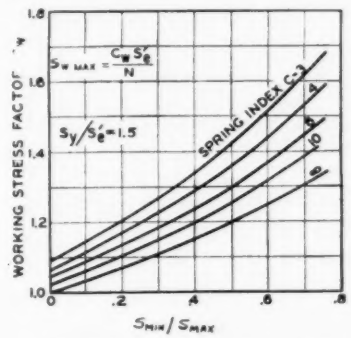

FIG. 4 CHART FOR DETERMINING THE WORKING-STRESS FACTOR C_w FOR $s_y/s'_e = 1.5$ AND $q = 1$ (FULL SENSITIVITY)

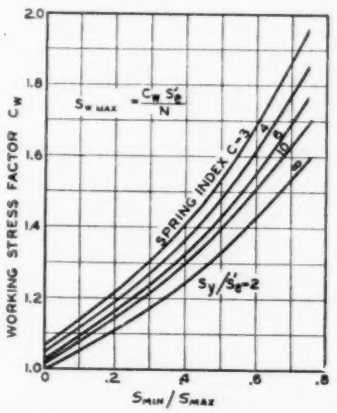

FIG. 5 CHART FOR DETERMINING THE WORKING-STRESS FACTOR C_w FOR $s_y/s'_e = 2$ AND $q = 1$ (FULL SENSITIVITY)

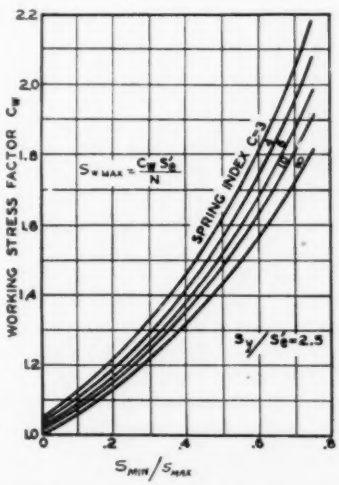

FIG. 6 CHART FOR DETERMINING THE WORKING-STRESS FACTOR C_w FOR $s_y/s'_e = 2.5$ AND $q = 1$ (FULL SENSITIVITY)

[14] The ultimate strength in torsion could be substituted for s_y if desirable. In some cases this would give results in closer agreement with tests, but the results obtained by using the yield point will, in general, be on the safe side.

[15] It is assumed that the variable component of stress is not greater than the static component, i.e., only stress conditions corresponding to the line PA in Fig. 3 are considered.

Charts showing the relation between C_w and s_{min}/s_{max} for various spring indexes at given values of s_y/s'_e are shown in Figs. 4, 5, and 6. Thus in Fig. 5 the ratio s_y/s'_e is taken equal to 2. These charts show clearly how the maximum permissible stress increases with increase in s_{min}/s_{max} and that this increase is greater for the springs of smaller index.

Method of Calculation Where Material Is Not Completely Sensitive to Stress Concentration

A similar procedure may be used for cases where the material is not completely sensitive to stress concentration. While fatigue tests on actual springs will be required to determine the actual sensitivity to stress concentration of the various materials made in various wire sizes, it may be expected that the sensitivity will be lower for the smaller wire sizes and for the coarser grained carbon steels, and higher for the larger sizes and the fine-grained alloy steels.

The sensitivity to stress concentration may be measured by the so-called "sensitivity index" q defined as[16]

$$q = \frac{K_f - 1}{K_c - 1} \quad [12]$$

where K_f is the fatigue strength reduction factor, i.e., the effective stress-concentration factor as determined by fatigue tests, and K_c is the theoretical stress-concentration factor as determined by strain measurements or mathematical analysis. For materials completely insensitive to stress-concentration, $K_f = 1$ and from Equation [12] $q = 0$, while for complete sensitivity $K_f = K_c$ and $q = 1$. Intermediate cases are represented by values of q between zero and unity.

To introduce the sensitivity index q in the expression for s_{max} in Equation [8], we note that in figuring the variable stress s_v we are to use the fatigue strength-reduction factor K_f rather than the theoretical stress-concentration factor K_c. But s_{max} and s_{min} have already been calculated by multiplying the nominal stress by the factor K which includes K_c. Hence, we must multiply the value given by Equation [5] by the ratio K_f/K_c. This gives

$$s_v = \left(\frac{s_{max} - s_{min}}{2}\right)\frac{K_f}{K_c} \quad [13]$$

But from Equation [12]

$$K_f = 1 + q(K_c - 1) \quad [14]$$

Substituting Equation [14] in Equation [13]

$$s_v = \left(\frac{s_{max} - s_{min}}{2}\right)\left(\frac{1 + q(K_c - 1)}{K_c}\right) \quad [15]$$

Using Equations [15] and [6] in Equation [7] we find

$$s_{max} = \frac{2s_y}{\frac{1}{K_c}\left(1 + \frac{s_{min}}{s_{max}}\right) + \left(\frac{2s_y}{s'_e} - 1\right)\left(1 - \frac{s_{min}}{s_{max}}\right)\left(\frac{1 + q(K_c - 1)}{K_c}\right)} \quad [16]$$

It is seen that where $q = 1$ (full sensitivity) Equation [16] reduces to Equation [8]. For $q = 0$ (no stress-concentration effect), the denominator of this equation is in effect divided by K_c, which means that stress-concentration effects due to curvature as represented by K_c are neglected entirely both for the static- and variable-stress components.

[16] See the second reference of footnote 11 for a discussion of "sensitivity index."

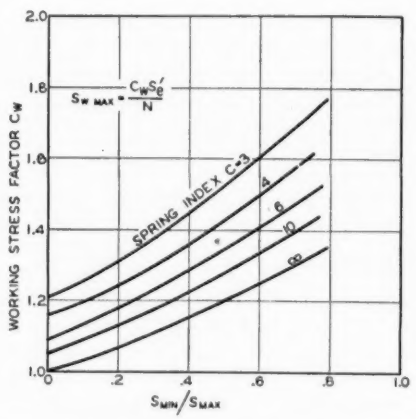

Fig. 7 Chart for Determining the Working-Stress Factor C_w for $s_y/s'_e = 1.5$ and $q = 1/2$

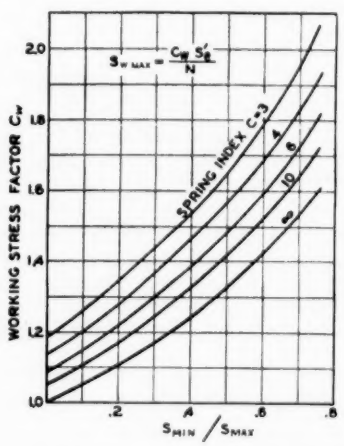

Fig. 8 Chart for Determining the Working-Stress Factor C_w for $s_y/s'_e = 2$ and $q = 1/2$

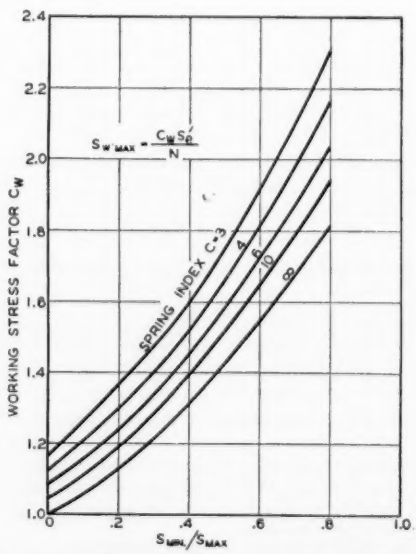

Fig. 9 Chart for Determining the Working-Stress Factor C_w for $s_y/s'_e = 2.5$ and $q = 1/2$

From Equation [16] we also obtain

$$C_w = \frac{2s_y/s'_e}{\frac{1}{K_c}\left(1+\frac{s_{min}}{s_{max}}\right)+\left(\frac{2s_y}{s'_e}-1\right)\left(1-\frac{s_{min}}{s_{max}}\right)\left(\frac{1+q(K_c-1)}{K_c}\right)} \quad \ldots . [17]$$

This also reduces to Equation [10] when $q = 1$.

Charts showing C_w as a function of spring index c for $q = 1/2$ and for s_y/s'_e equal to 1.5, 2.0, and 2.5 are given in Figs. 7, 8, and 9, respectively. These charts are given merely as examples to show the effect of a reduction in the sensitivity of the material, as measured by the index q, on the allowable stress.

Example of Application of Charts

To illustrate the application of the charts shown in Figs. 4, 5, and 6 in practical work, let us assume we have a spring of 1/4-in. wire diameter and 3/4-in. mean coil diameter, i.e., $c = 3$. Assume that fatigue tests on springs of large index and on the same size wire subjected to a pulsating load (zero to maximum) yield of value of endurance limit $s'_e = 60{,}000$ lb per sq in., while torsion tests show a yield point in torsion[17] of 120,000 lb per sq in. Assume further that the spring is under a fatigue range from s_{min} to s_{max}, where $s_{min} = 0.5\, s_{max}$. To be on the safe side, we assume full sensitivity of the material ($q = 1$). Since $s_y/s'_e = 2$, we use the chart shown in Fig. 5 and from this chart for $c = 3$, $s_{min}/s_{max} = 1/2$, we find $C_w = 1.53$. Thus, from Equation [9], we may on this basis expect fatigue failure at $s_{max} = C_w s'_e = 1.53 \times 60{,}000 = 92{,}000$ lb per sq in. Assuming a factor of safety $N = 1.5$, the working stress, from Equation [11], would be $s_{w_{max}} = C_w s'_e/N = 92{,}000/1.5 = 61{,}000$ lb per sq in., this stress being calculated by using the K-factor of Fig. 1. If the spring index were 10 instead of 3, the factor C_w would, from Fig. 5, be 1.39 and the working stress $s_{w_{max}} = (1.39 \times 60{,}000)/1.5 = 56{,}000$ lb per sq in., assuming a factor of safety $N = 1.5$.

To show the effect of a reduction in the q factor, let us assume that endurance tests on springs of smaller index in this particular wire size show a value of $q = 1/2$. Then, using the chart shown in Fig. 8, ($s_y/s'_e = 2$, $q = 1/2$) we find $C_w = 1.65$ for $c = 3$ and $s_{min}/s_{max} = 1/2$. In this case, the allowable working stress, using a factor of safety $N = 1.5$, would be $s_{w_{max}} = C_w s'_e/N = (1.65 \times 60{,}000)/1.5 = 66{,}000$ lb per sq in.

Discussion of Limitations of Method for Finding C_w

The method of design previously discussed is based on the assumption of a linear relation between the static- and variable-stress components necessary to cause fatigue failure, i.e., the line PA in Fig. 3 is assumed. Usually the experimental results will be somewhat above this line as indicated. Hence, if the value of the zero to maximum endurance limit s'_e were determined by actual tests on a spring of large index and having the wire size under consideration, it appears that if the line PA were used as a basis the results would be on the safe side. In this connection it is necessary to determine the value of s'_e by tests on the actual wire size used, since the endurance values may change considerably between small and large sizes. It has also been assumed that the line of failure PA tends to approach the yield point in torsion. In some cases it may be found that this line tends to approach the ultimate strength in torsion.[18] In such cases the ultimate strength s_u could be used instead of s_y in applying the charts and formulas. If this were done, however, a higher factor of safety should be used than would be the case otherwise.

In deriving the formulas for C_w, it has been assumed that the endurance properties of the material do not change between springs of small and large index, assuming a given wire size. Although this appears to be a reasonable assumption, there are cases where it may not be strictly true. For example, in cold-wound springs made from a given size of wire, the springs coiled to the smaller diameters will be subjected to the greatest amount of cold working; hence, such springs may possess somewhat different endurance properties than would otherwise be expected. If a stress-relieving treatment were given, this difference would possibly be slight. A similar result may be expected where springs are quenched after coiling, since the effect of the heat treatment may be different for springs of different indexes.

It is common practice, in the manufacture of compression springs, to compress the spring solid, thus giving it a permanent set. The effect of this is to introduce residual stresses of opposite sign so that when the spring is under the working load, the peak stress will be reduced by the amount of such residual stresses. For this reason the tendency will be for the fatigue strength to be increased because of the presence of these stresses. Because of the sharper curvature of the springs having smaller indexes, it will be easier to introduce such residual stresses in these springs, and for this reason it may happen that the fatigue strength of the springs of smaller index may be increased by such treatment to a relatively greater extent than is the case for springs of large index. Such effects may be taken into account by changes in the sensitivity index q when more test data are available.

In the present analysis, the effects of eccentricity of loading due to the presence of the end turns have been neglected. Some years ago the author had occasion to make a series of tests to determine eccentricity of loading in small helical springs in compression. It was found that such eccentricities may increase the maximum stress from 4 to 30 per cent, depending on the shape and form of the end turns, and the total number of turns; considerable scatter was evident in the results. For an accurate check of the effects of wire curvature on the endurance, it would seem desirable to make provision for applying central loads to springs under fatigue test in order to eliminate the disturbing effects due to eccentricity of loading which may tend to mask the effects due to wire curvature. In this connection, reference may be made to the torsional fatigue tests carried out on spring wires by Weibel.[19] These tests showed endurance limits in zero to maximum torsion of about 105,000 lb per sq in. compared with values around 65,000 lb per sq in. obtained on complete springs made from the same material by Zimmerli.[18] As mentioned by Weibel, part of this difference may be due to internal stress in the cold-wound spring and part may be due to the greater probability of the presence of serious flaws in the complete spring. It is the author's opinion, however, that eccentricity of loading of the complete spring may also play an important part in explaining this very considerable difference. Such eccentricity would lower the endurance limit of the complete spring in comparison to that which is obtained in simple torsion tests on straight specimens.

Comparison With Test Results

To the author's knowledge the most comprehensive series of tests yet made to check the effect of spring index on endurance strength of helical springs are those carried out by Zimmerli[6] who made a series of tests on springs of 0.148-in. diameter pre-

[17] If the yield point is not sharply defined it may, as an approximation, be taken as that point where the plastic strain is 0.2 per cent. See the paper: "Concerning the Yield Point in Tension," by J. M. Lessells, Proceedings of the American Society for Testing Materials, vol. 28, part 2, 1938, p. 387.

[18] "Permissible Stress Range in Small Helical Springs," by F. P. Zimmerli, Engineering Research Bulletin No. 26, University of Michigan, Ann Arbor, Mich.

[19] "The Correlation of Spring-Wire Bending and Torsion Fatigue Tests," by E. E. Weibel, Trans. A.S.M.E., vol. 57, November, 1935, paper RP-57-1, pp. 501–516.

tempered Swedish valve-spring wire with indexes c varying from 3.5 to 12. It will be of interest to compare these test results with those obtained by the application of the charts shown in Figs. 4, 5, and 6, which assume full sensitivity to stress concentration ($q = 1$). Values of the minimum and maximum points (s_{min} and s_{max}) of the limiting stress ranges as found by Zimmerli[6] for the various indexes are given in the second and third columns of Table 1. To determine the zero to maximum endurance limit s'_e, for a spring of large index, we use the test results for $c = 11.9$ as a basis, taking $s_{min} = 19{,}000$ lb per sq in., $s_{max} = 91{,}000$ lb per sq in., and $s_{min}/s_{max} = 0.21$. Assuming tentatively $s_y/s'_e = 1.5$, we find, from Equation [8], $s_{max} = 1.11\, s'_e$ for $s_{min}/s_{max} = 0.21$. Solving, $s'_e = 91{,}000/1.1 = 82{,}700$ lb per sq in. Since the yield point in torsion for this material will be around 120,000 lb per sq in. (or somewhat above the elastic limit in torsion) we may assume $s_y/s'_e = 1.5$ with sufficient accuracy and use the chart shown in Fig. 4. Using this value of s'_e and assuming the minimum values of the stress range (s_{min}) as given, the limiting values of maximum stress s_{max} were computed using the chart shown in Fig. 4 and Equation [9]. (Equation [8] may also be used for calculation.) The computed values of s_{max} thus found are given in the fifth column of Table 1. For comparison, values of the limiting stress range $s_{max} - s_{min}$ as found by Zimmerli,[6] and as determined by calculation, are given in the last two columns of Table 1.

TABLE 1

Spring Index c	Limiting stresses[a] from Zimmerli's fatigue tests[b]		Calculated values of limiting stresses (using Fig. 4)		Limiting range in stress $s_{max} - s_{min}$	
	s_{min}	s_{max}	s_{min}	s_{max}	By test (Zimmerli)[b]	Calculated (Fig. 4)
3.50	14000	100000	14000	95500	86000	81500
4.55	19000	94000	19000	96000	75000	77000
7.00	19000	93000	19000	93500	74000	74500
9.10	19000	90000	19000	92000	71000	73000
11.90	19000	91000	19000	91000	72000	72000

[a] These stresses figured using the K-factor.
[b] See footnote 6.

A comparison of the figures in the last two columns of Table 1 indicates that the test and calculated values of limiting stress range differ by only a few per cent. This offers some indication that the method of determining working stress by using Equation [8], which assumes full sensitivity to stress concentration ($q = 1$), will give results in fair agreement with actual fatigue tests, at least for some materials and wire sizes.

The tests by Edgerton mentioned previously[7] were made on two groups of springs coiled from $^3/_4$-in. diameter bar stock, one group of index 3 and the other of index 5. The endurance limits calculated by the use of the conventional formula were practically the same for the two groups of springs, while the endurance limits calculated by using the K-factor differed considerably. This would indicate that for these springs neither the bar curvature nor the direct shear stress have any effect on the endurance. As mentioned by Edgerton,[7] this is a most surprising conclusion, and further check tests are necessary. Since the tests by Zimmerli[6] discussed previously do show a definite effect on the endurance properties produced by wire curvature, even in small springs, it would seem that a more comprehensive series of tests should be made before drawing definite conclusions. In particular it would seem desirable to carry out a series of tests in which provision is made to obtain a centrally applied load on the spring in order to eliminate as much as possible the disturbing effects due to eccentricity of loading which, as mentioned previously, may tend to mask the effects produced by wire curvature.

Conclusions

The method described in this paper for determining the effect of bar or wire curvature on working stresses in helical springs under fatigue loading is suggested as a rational basis for the application of our present knowledge of the endurance properties of materials to this problem. While it is realized that the method may have to be modified in the light of future test results, it appears to yield reasonable results in certain cases when applied to existing fatigue-test data. Further fatigue tests wherein eccentricity of loading is eliminated would appear desirable in order to obtain a more accurate determination of the sensitivity index q for various wire sizes and spring materials. For design purposes, an additional factor to take eccentricity of loading into account may be introduced, but a discussion of this is beyond the scope of the present paper.

Acknowledgment

The author wishes to express his appreciation to L. W. Chubb and R. E. Peterson of the Westinghouse Research Laboratories for their interest and suggestions in connection with the preparation of this paper.

Discussion

Practical Aspects of Turbine Cylinder Joints[1]

GEORGE L. BASCOME.[2] The author's remarks relative to several factors which must be considered in the design of the longitudinal joint of a steam-turbine casing, subjected to high pressure and temperature, apply as well to a bolted flanged joint for steam piping.

Some years ago the writer was engaged in the testing of various types of flanged joints under consideration for a 1500-lb 900 F installation, for the power station of the Houston Lighting and Power Company. These tests were conducted jointly by the engineers of the utility and the fabricating companies responsible for the installation of the piping. At that time little was known concerning the behavior of the steel at high temperatures, so that in conducting these tests nothing was taken for granted, and careful micrometer measurements were made of bolts and flanges before and after each test. Thermocouple attachments were made at various locations about each joint, in order that temperature changes might be noted between the several parts.

At the beginning, it was felt that a type of joint, with ground faces, without a gasket would prove most satisfactory, but within a few hours the joint leaked. A close examination showed that due to the high temperature a slight warping of ground faces had occurred. This indicated that a metal-to-metal type of joint for this class of service should be thoroughly stress-relieved prior to finishing the surfaces. It is not recalled that the author made mention of this fact, but I presume that the turbine casings are stress-relieved prior to machining, in order to prevent distortion from heat under operating conditions.

In order to determine the best bolting material and a safe working stress, a crude but satisfactory relaxation-test method was employed. The bolts were stressed to 40,000 lb per sq in., between the faces of a cylindrical sleeve, or cage, carefully micrometered, and then submerged for a week in melted lead at 900 F. At the end of the period the increase in bolt length over the initial length was noted. This information determined the bolting steel best fitted for this service and also the permissible stress which might be employed. Micrometer measurements of the bolts during erection insured that proper unit pressure was provided to the joint faces.

The author stated that a net unit pressure between joint faces of the turbine casings of three times the internal pressure was necessary to maintain a tight joint under loaded conditions. The tests on pipe joints just referred to, indicated that the net pressure need be between two and three times the internal pressure when the joint was under pressure, including calculated bending moments. It is surprising that these early tests made with limited facilities should agree so closely with the author's findings.

It might be stated that the final design of the joint for this installation included a thin gasket to care for any slight warping of the joint faces, with a calculated gasket area, such as to provide the suitable net unit pressure with a safe working stress in the bolting material. It was stated that no leakage occurred during the first two years of service in any of the joints so designed and erected.

In conclusion it seems that if due consideration is given to all factors, a bolted joint can be designed to meet the most exacting service, and such information as was disclosed by the author is of great value to the profession.

C. RICHARD SODERBERG.[3] The relation between bolt pitch and flange dimensions which is given in the equation $t \geqq \sqrt{\left[d^2 + \left(\frac{P}{2}\right)^2\right]}$ appears somewhat arbitrary, although it is probably a safe working rule. The following presents a point of view which throws further light on this important question.

In a straight joint of the type shown in Fig. 3 of the paper, the flange may be represented as a double beam, each half of dimensions $b \times h$ held together by a series of concentrated forces P produced by the bolts. See Fig. 1 herewith. The material between the neutral axes of the beams is elastic under the influence

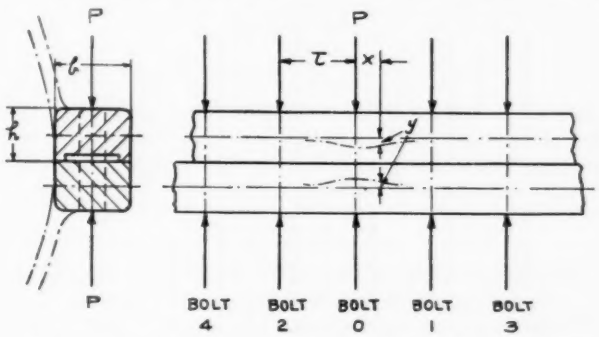

FIG. 1 STRAIGHT JOINT WITH CONCENTRATED BOLT LOADS

of the compression forces. Considering one of these beams, therefore, it may be regarded as supported on an elastic foundation, the modulus of which is

$$k = \frac{2Eb}{h} \text{ lb per sq in.} \quad [1]$$

The influence of relief and bolt holes will be neglected, although there are no serious difficulties in taking these into account, at least approximately. If the two beams deflect symmetrically toward each other a distance y, the resulting compression load per unit length is

$$q = ky \text{ lb per in.} \quad [2]$$

Thus, if the deflection of the beam can be expressed as a function of x, the resulting load distribution is also obtained.

The theory for a beam on an elastic foundation is well known,[4] and the results may be used to gain an insight into the present problem. Considering first the effect of a single force P in a long beam, the results of this theory give for the load distribution

$$q = q_0\varphi \quad [3]$$

where φ is a function of βx.

$$\varphi = e^{-\beta x} (\cos \beta x + \sin \beta x) \quad [4]$$

$$\beta = \sqrt[4]{\left(\frac{k}{4EI}\right)} = \frac{\sqrt[4]{6}}{h} = \frac{1.565}{h} \quad [5]$$

and

$$q_0 = \frac{Pk}{8\beta^3 EI} = \frac{\sqrt[4]{6}}{2}\frac{P}{h} = 0.783\frac{P}{h} \quad [6]$$

This distribution is shown in Fig. 2. At about $\beta x = 2.4$, the load becomes zero, and for larger values it is negative. Negative

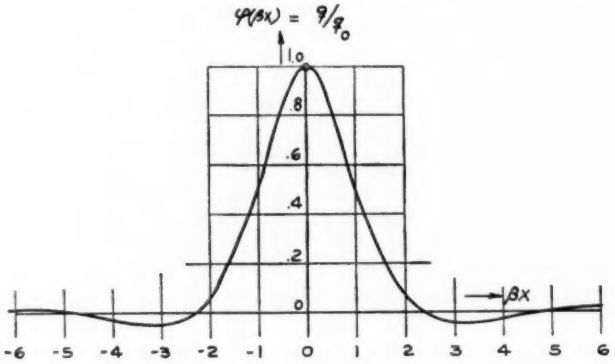

FIG. 2 LOAD DISTRIBUTION OF ONE BOLT

loads are excluded for practical reasons, but this is not serious since the case of a single bolt has only theoretical interest. The characteristic feature of the load distribution lies in the fact that it is a periodic function having a wave length

$$L = 2\pi/\beta \approx 4h \quad [7]$$

To obtain the load distribution for a series of bolts spaced at a pitch τ, it is necessary to add a series of such functions. The convergence is rapid for the pitches of practical interest, so that only a few terms are necessary. For convenience, it is assumed that the pitch is made a certain fraction ν of the wave length, so that

$$\tau = \nu L \quad [8]$$

Referring to Fig. 1, it is easily seen that the load distribution becomes

$$\begin{aligned} &\text{Bolt 0} \qquad \text{Bolts 1,3, ...} \qquad \text{Bolts 2,4, ...} \\ q = q_0 [\varphi(\beta x) &+ \varphi(2\pi\nu - \beta x) + \varphi(2\pi\nu + \beta x) \\ &+ \varphi(4\pi\nu - \beta x) + \varphi(4\pi\nu + \beta x) + \ldots.] \end{aligned} \quad [9]$$

where q_0 represents the maximum load due to a single bolt.

Fig. 3 shows the load distributions obtained in this manner for $\nu = \tau/L = \infty$, $^3/_4$, $^1/_2$, $^3/_8$, and $^1/_4$. Fig. 4 shows the ratio of q_{min}/q_{max} plotted as a function of ν.

These results must be regarded in the light of rough approximations of the real problem, but they permit the following conclusions:

1 The longitudinal load distribution is a sensitive function of the ratio of flange thickness h to bolt pitch τ.

2 The load midway between two bolts will fall to zero if the bolt pitch is greater than $(^3/_4)L = 3h$, which corresponds to

$$h \leq (^1/_3)\tau \quad [10]$$

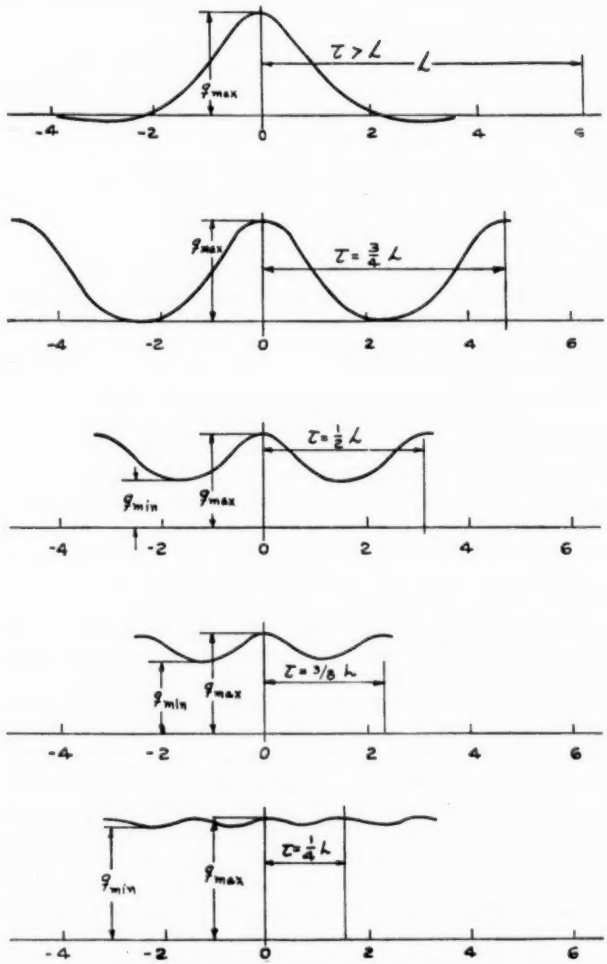

FIG. 3 LOAD DISTRIBUTION FOR VARIOUS VALUES OF $\nu = \tau/L$

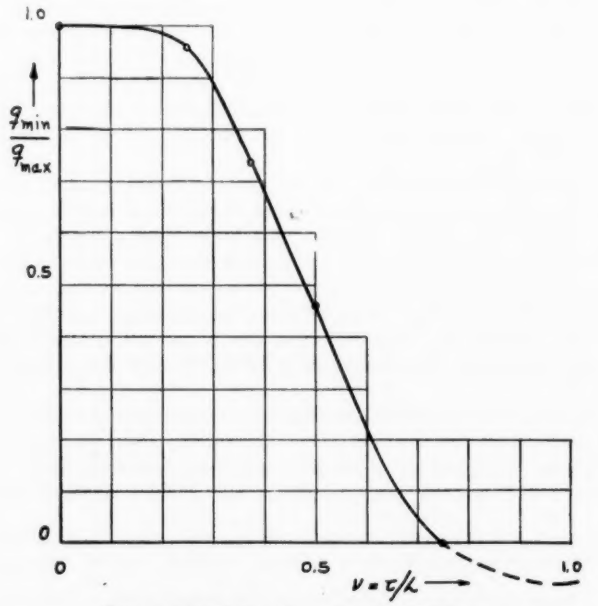

FIG. 4 RATIO q_{min}/q_{max} AS A FUNCTION OF ν

Flange thicknesses equal to or below this value must be regarded as definitely unsatisfactory.

3 In order to obtain approximately uniform load distribution along the flange, it is necessary that the bolt pitch be greater than $(1/4)L$, which corresponds to

$$h \geqq \tau \quad \ldots\ldots [11]$$

A satisfactory simple rule, therefore, is to make flange thickness and bolt pitch equal.

It is important to note that the width of the flange does not influence the longitudinal load distribution. This is not true, of course, if the flange is made so wide as to have appreciable deflection over the relieved portion. The design rules proposed by the author will satisfactorily guard against this.

Author's Closure

Mr. Bascome is correct in assuming that the turbine cylinder casings are stress-relieved prior to final machining.

As stated by Mr. Soderberg, the relation between bolt pitch and flange thickness $h \geqq \sqrt{\left[d^2 + \left(\frac{P}{2}\right)^2\right]}$ is arbitrary, and is purely a rule of thumb which results in rational and well proportioned design. Combined with Mr. Soderberg's conclusion that flange thickness should be equal to or greater than the bolt pitch, we find that the distance d, Fig. 3 of the original paper, should not exceed 0.9 × bolt pitch, an entirely rational result.

Stress Model of a Complete Airship Structure[1]

L. B. Tuckerman.[2] The evident care and foresight used by the authors cannot but impress anyone who appreciates the pitfalls which may lie on the path from test to structure. It would be difficult to find any essential property of their model which has been overlooked.

The discussion of the scales N is complete, and it is particularly gratifying to find second-order effects associated with buckling considered adequately. The model girder is ingenious, with its slotted tubes so placed that advantage is taken of the slot to reduce the torsional stiffness without affecting the flexural stiffness. Finally, the spacing of the tubes in the middle solves well the problem of controlling the axial stiffness.

A nice instance of the care exercised is shown in the method used in soldering the wires and allowing for the reduced tension in the bulkhead wires due to the installation of the shear wires. In speaking of the wires, it is the hope of the writer that the authors will publish a full description of their specially designed tensometer for measuring the tension in a taut wire. The writer has seen what he believes is this instrument or one like it, and it should be better known.

The many check tests, and especially those which lead to the results shown in Figs. 14, 15, and 16 inspire confidence. It is easy to say that the precautions taken throughout are fairly evident. So they are in many cases after they have been pointed out. Unfortunately, however, much testing is done in which adequate consideration is not given to what should be evident. It is a pleasure to find an experimental investigation carried out with the attention to important detail which the authors have shown.

An Improved Method for Calculating Free Vibrations in Systems of Several Degrees of Freedom[1]

Geometric Interpretations of the Method of Successive Approximations

M. A. Biot.[2] The method of successive approximations using matrix algebra is based on the same fundamental principles as what is generally known as Vianello's or Stodola's method. Starting from an arbitrary deflection of the system, the corresponding dynamic forces are evaluated assuming a given angular frequency, for instance, $\omega = 1$. A new set of deflections due to these dynamic forces is found, and with this new set, the process can be repeated. A certain number of such processes leads toward a convergent shape of the deflection, which is the shape of the fundamental mode, and the ratio of two successive deflections is equal to the square of the fundamental angular frequency.

It will be shown hereafter that a simple geometrical interpretation exists for this method.

Consider a system of two masses m_1 and m_2 connected to each other and to a fixed base B by springs, as shown in Fig. 1. It is assumed that there are only two degrees of freedom determined by the displacements x_1 and x_2 of the masses.

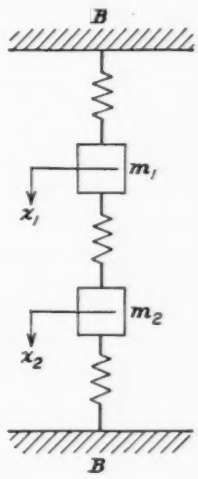

Fig. 1

Two loads P_1 and P_2 applied, respectively, to the masses m_1 m_2 produce deflections

$$\left.\begin{aligned} x_1 &= d_{11}P_1 + d_{12}P_2 \\ x_2 &= d_{21}P_2 + d_{22}P_2 \end{aligned}\right\} \quad \ldots\ldots [1]$$

when the d's are the influence numbers. According to Maxwell's reciprocity theorem, we have

$$d_{12} = d_{21} \quad \ldots\ldots [2]$$

The elastic potential energy under the loads P_1 P_2 is

$$W = \tfrac{1}{2}(x_1P_1 + x_2P_2) = \tfrac{1}{2}[d_{11}P_1^2 + 2d_{12}P_1P_2 + d_{22}P_2^2] \ldots [3]$$

Equations [1] of this discussion may be written as

$$\left.\begin{aligned} x_1 &= \partial W/\partial P_1 \\ x_2 &= \partial W/\partial P_2 \end{aligned}\right\} \quad \ldots\ldots [4]$$

For the sake of simplicity let us first assume that the two masses are both equal to unity. The problem of finding the natural vibrations of our system will be solved if we know values of P_1 and P_2 such that they are proportional to the displacements x_1 and x_2 produced by these forces, that is

$$P_1/x_1 = P_2/x_2 = \omega^2 \quad \ldots\ldots [5]$$

This follows from the fact that $\omega^2 x_1$ and $\omega^2 x_2$ are the inertia forces when the angular frequency is ω.

This problem is illustrated geometrically as follows:

Consider a coordinate system P_1 P_2. Equations [1] of this discussion define a linear transformation of the vector P of components P_1 P_2 into a vector X of components x_1 x_2. The vector X

[1] By Winston M. Dudley. Published in the June, 1938, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 60, 1938, p. A-61.

[2] Professor, Department of Physics, Columbia University, New York, N. Y.

is a so-called linear vector function of P. The natural vibrations will correspond to those directions for which the vectors P and X are parallel.

Because of the symmetric character ($d_{12} = d_{21}$) of its coefficients, the transformation Equations [1] are associated with a certain conic

$$W = {}^1/_2[d_{11}P_1^2 + 2d_{12}P_1P_2 + d_{22}P_2^2] = \text{const}. \quad [6]$$

in the coordinate system $P_1\,P_2$. If we rotate the coordinate axes so as to make them coincide with the axes of the conic, the vector P is expressed by new components $\overline{P}_1\,\overline{P}_2$ and the equation of the conic becomes

$$W = {}^1/_2[D_{11}\overline{P}_1 + D_{22}\overline{P}_2^2] \quad [7]$$

Since the elastic potential energy is positive, D_{11} and D_{22} must be positive and the conic defined by Equation [6] must be an ellipse.

Equations [4] show that the linear vector function, expressed by

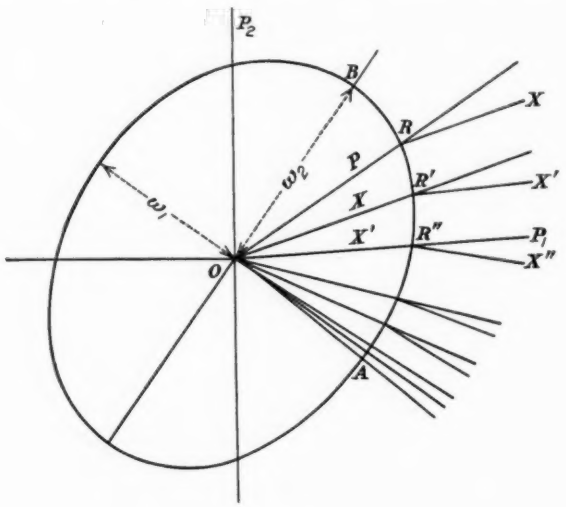

FIG. 2

Equations [1], is entirely defined by the scalar function W. They may be written in the form

$$X = \text{grad}\, W \quad [8]$$

They also show that when P is in the direction of a radius vector OR of the ellipse, then X is parallel with the normal to the ellipse at point R, as shown in Fig. 2.

Equation [5] will therefore be satisfied if we choose P in the direction of one of the axes of the ellipse. Hence, these directions determine the natural vibrations of our system.

The small axis corresponds to the lower frequency. This can be seen from Equations [7] and [8]. Along the axis $\overline{P}_1$ we have

$$\bar{x}_1 = \partial W/\partial \overline{P}_1 = D_{11}\overline{P}_1$$

According to Equation [5], $D_{11} = 1/\omega_1^2$ where ω_1 is the natural angular frequency corresponding to the axis $\overline{P}_1$. In the same way, if ω_2 is the angular frequency corresponding to the axis $\overline{P}_2$ we have

$$D_{22} = 1/\omega_2^2$$

The equation of our ellipse is

$$\frac{\overline{P}_1^2}{\omega_1^2} + \frac{\overline{P}_2^2}{\omega_1^2} = \text{const} \quad [9]$$

The axes are proportional to the corresponding natural frequencies.

The problem of finding the natural vibrations of our system is reduced to that of finding the direction of the axis of the ellipse defined by Equation [6].

The point which we finally want to stress is that the direction of the minor axis may be found by a method of successive approximations, which is fundamentally the same as the matrix method explained by the author in his paper,[1] and may also be considered as the geometrical illustration of what is generally known in the literature as Vianello's or Stodola's method.

Considering the ellipse defined by Equation [6] and shown in Fig. 2, we start with a vector P lying along the radius vector OR and draw a vector X in the direction of the normal to the conic at R. Now we take a radius vector OR' parallel with X and obtain by the same process a vector X'. Taking a radius-vector OR'' parallel with X' we find a new vector X'', and so on. It can be seen that the direction of these successive vectors will converge toward the direction of the smaller axis.

According to Equation [5], the ratio of the successive values of x will tend toward ω_1^2, the square of the fundamental angular frequency.

We have supposed the masses to be equal, but, as we shall see, this is not a restriction. Suppose the masses to be respectively m_1 and m_2. The transformation Equations [1] will be replaced by

$$\left.\begin{aligned} x_1' &= d_{11}m_1x_1 + d_{12}m_2x_2 \\ x_2' &= d_{21}m_1x_1 + d_{22}m_2x_2 \end{aligned}\right\} \quad [10]$$

The natural vibrations will be determined by a solution of this system such that

$$x_1'/x_1 = x_2'/x_2 = \omega^2 \quad [11]$$

We note that the coefficients of the transformation Equations [10] are not symmetric. However, they can be made symmetric by a simple change of variable. They may be written

$$\left.\begin{aligned} \xi_1' &= d_{11}m_1\xi_1 + d_{12}\sqrt{m_1m_2}\,\xi_2 \\ \xi_2' &= d_{21}\sqrt{m_2m_1}\,\xi_1 + d_{22}m_2\xi_2 \end{aligned}\right\} \quad [12]$$

with $x_1'\sqrt{m_1} = \xi_1'$; $x_1\sqrt{m_1} = \xi_1$; $x_2'\sqrt{m_2} = \xi_2'$; and $x_2\sqrt{m_2} = \xi_2$. The ellipse associated with the transformation is defined by the equation

$$d_{11}m_1\xi_1^2 + 2d_{12}\sqrt{m_1m_2}\,\xi_1\xi_2 + d_{22}m_2\xi_2^2 = \text{const}$$

The general case is hereby reduced to the one with equal unit masses, studied previously in this discussion.

Using the matrix notation, the transformation Equations [12] are written as

$$\begin{Bmatrix} \xi_1' \\ \xi_2' \end{Bmatrix} = \begin{Vmatrix} d_{11}m_1 & d_{12}\sqrt{m_1m_2} \\ d_{21}\sqrt{m_2m_1} & d_{22}m_2 \end{Vmatrix} \begin{Bmatrix} \xi_1 \\ \xi_2 \end{Bmatrix} \quad [12]'$$

For a system with three degrees of freedom, the transformation would be

$$\begin{Bmatrix} \xi_1' \\ \xi_2' \\ \xi_3' \end{Bmatrix} = \begin{Vmatrix} d_{11}m_1 & d_{12}\sqrt{m_1m_2} & d_{13}\sqrt{m_1m_3} \\ d_{21}\sqrt{m_2m_1} & d_{22}m_2 & d_{23}\sqrt{m_2m_3} \\ d_{31}\sqrt{m_3m_1} & d_{23}\sqrt{m_3m_2} & d_{33}m_3 \end{Vmatrix} \begin{Bmatrix} \xi_1 \\ \xi_2 \\ \xi_3 \end{Bmatrix} \quad [13]$$

with the variables $\xi_i' = x_i'\sqrt{m_i}$ and $\xi_i = x_i\sqrt{m_i}$.

The associated surface is here an ellipsoid with axis proportional to the three natural frequencies. The transformation Equations [13] define a linear vector function ξ' of ξ. Drawing a radius vector OR of the ellipsoid in the direction of ξ, the vector ξ' will be parallel with the normal to the ellipsoid at R. Applying the same transformation of direction to ξ', we obtain a new direc-

tion ξ'' and so on. It can be seen that by this process we travel along the ellipsoid and we will tend to reach the smallest axis, and hence, the fundamental mode of vibration of the system. However, if we start the process with a vector ξ lying in the plane of the medium axis and the biggest axis, the process will lead us to the medium axis or the first harmonic. Starting with a vector ξ having no component along the minor axis of the ellipsoid means that we start the process of successive transformations with a set of deflections from which the fundamental mode is completely eliminated.

In practice, however, it is never possible to eliminate exactly the fundamental mode, and the process will lead toward a direction which might become very close to that of the medium axis, but will finally converge toward the minor axis along a path *DEA* shown in Fig. 3. An improved method is to eliminate at every step the component along the minor axis. It is shown in the paper[1] how this can be done. The elimination of the component along the minor axis may be affected by expressing that the scalar product of the vector $\xi(\xi_1\xi_2\xi_3)$ and the vector $\alpha(\alpha_1\alpha_2\alpha_3)$ along the minor axis is zero.

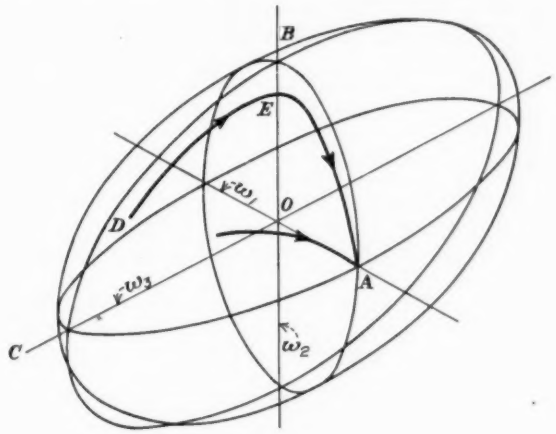

FIG. 3

$$\xi_1\alpha_1 + \xi_2\alpha_2 + \xi_3\alpha_3 = 0$$

or since $\alpha_i = \sqrt{m_i}\, a_i$, where a_i are the deflections of the fundamental mode

$$\Sigma m_i x_i a_i = 0 \ldots\ldots\ldots\ldots\ldots\ldots [14]$$

which is the expression [12] found by the author in his paper.[1] It has the same form as Equation [21] of this discussion in the theory of orthogonal functions. In the case of a system of n degrees of freedom the analogy will apply for an ellipsoid in n-dimensional space.

Relation With the Properties of Orthogonal Functions

A load $p(x)$ per unit length applied to a one-dimensional elastic system as a beam or a string produces a deflection

$$w(x) = \int_0^l g(x\xi)p(\xi)d\xi \ldots\ldots\ldots\ldots\ldots [15]$$

where $g(x\xi)$ is the influence number. We have

$$g(x_1\xi) = g(\xi_1 x)$$

The transformation Equations [1] correspond to the transformation Equation [15]. Introducing dynamic forces

$$p(x) = \omega^2\rho(x)\, w(x)$$

where $\rho(x)$ is the mass per unit length, we find the integral equation

$$w(x) = \omega^2 \int_0^l \rho(\xi)\, g(x\xi)\, w(\xi)\, d\xi \ldots\ldots\ldots [16]$$

which corresponds to the matrix Equation [3] of the paper,[1] $\{w\} = \omega^2[d][m][w]$.

The dynamical matrix $[d][m]$ corresponds to $g(x\xi)\rho(x)$ in the integral Equation [16] of this discussion. The mode of vibrations $w_i(x)$ and the corresponding frequencies ω_i are solutions of the integral Equation [16] of this discussion. The functions $w_i(x)$ are orthogonal, and satisfy the relation

$$\int_0^l \rho(x)\, w_i(x)\, w_j(x)\, dx = 0 \ldots\ldots\ldots\ldots [17]$$

where $i \neq j$. This corresponds to the relation given later in Equation [18] of this discussion. It may be considered as the mathematical formulation of the fact that the axis of the associated ellipsoid are orthogonal. In the example given in this discussion, for instance, if $\xi_1^0\ \xi_3^0\ \xi_3^0$ and $\xi_1'\ \xi_2'\ \xi_3'$ are the components of two of the axes of our ellipsoid, we have

$$\Sigma\xi_i^0\xi_i' = 0$$

or

$$\Sigma m_i x_i^0 x_i' = 0 \ldots\ldots\ldots\ldots\ldots [18]$$

An arbitrary deflection $w(x)$ may be developed into a series of orthogonal functions

$$w(x) = A_0w_0(x) + A_1w_1(x) + \ldots\ldots A_nw_n(x) \ldots\ldots [19]$$

The coefficients are determined by the expression

$$A_i = \frac{\int_0^l \rho(x)\, w_i(x)\, w(x)\, dx}{\int_0^l \rho(x)\, w_i^2(x)\, dx}$$

If we apply to $w(x)$ the transformation

$$w'(x) = \int_0^l \rho(\xi)\, g(x\xi)\, w(\xi)\, d\xi \ldots\ldots\ldots [20]$$

each function $w_i(x)$ in the series of Equation [19] is transformed into $w_i(x)/\omega_i^2$, and

$$w'(x) = \frac{A_0}{\omega_0^2} w_0(x) + \frac{A_i}{\omega_1^2} w_1(x) + \ldots\ldots\ldots\ldots \frac{A_n}{\omega_n^2} w_n(x)$$

Applying this transformation a sufficient number of times we find[2]

$$w^{(k)}(x) = \frac{1}{\omega_0^{2k}}\left[A_0w_0(x) + A_1\left(\frac{\omega_0}{\omega_1}\right)^{2k} w_1(x) + \ldots\ldots\right]$$

Hence the shape of $w^{(k)}(x)$ tends toward that of the fundamental mode $w_0(x)$ if $A_0 \neq 0$ and we also have

$$\frac{w^{(k)}(x)}{w^{(k+1)}(x)} \to \omega^2$$

If we want the deflection to converge toward the first harmonic, we must choose an initial deflection $w(x)$ such that $A_0 = 0$, or

$$\int_0^l \rho(x)\, w_0(x)\, w(x)\, dx = 0 \ldots\ldots\ldots\ldots [21]$$

The initial transformation Equation [20] corresponds to the linear transformation

$$\{w'\} = [d][m][w] \ldots\ldots\ldots\ldots\ldots [22]$$

and the condition given by Equation [21] corresponds to the relation expressed by Equation [14].

[2] "Mechanical Vibrations," by J. P. DenHartog, McGraw-Hill Book Company, New York, N. Y., 1934, p. 179.

The method of successive approximation was first suggested in 1898 without much justification by Vianello[4] in connection with the buckling problem of a beam and the equation

$$Dw(x) + Pw(x) = 0$$

where D denotes a differential operator. This is essentially the same method as that derived from the integral equation. In fact, the integral equation is equivalent to a very general class of differential equations of the type

$$Dw(x) + \omega^2\rho(x)\, w(x) = 0 \quad \ldots\ldots\ldots\ldots [23]$$

Such parallelism between the properties of systems with a finite number of degrees of freedom and continuous systems was to be expected since the integral equation can be considered as the limiting case of a system of linear equations with an infinite number of variables.

C. Concordia.[5] It may be pointed out that Mr. Dudley's methods, although developed only for a system of point masses, may be extended to systems having also rotary inertia. Then the mass matrix (i.e., the components of the mass tensor along the reference frame in question) in the last equation on page A-61 of his article will in the general case be the sum of a mass matrix having nonzero components only in the main diagonal and a moment-of-inertia matrix all of whose components may be nonzero. Such a general mass matrix is illustrated in Equations [11] and [17] of the article "The Use of Tensors in Mechanical Engineering Problems," *General Electric Review*, vol. 39, July, 1936, p. 335. The form having only main diagonal components can, of course, always be obtained by transforming either to normal system coordinates or to the principal axes of each rigid body of the system.

Author's Closure

Mathematically inclined readers should be helped to an understanding of the method of successive approximations by Professor Biot's geometrical interpretation of it. He also points out that when the number of degrees of freedom of a system is increased to infinity, we pass from a matric grouping of linear equations to a single integral equation. This may lead to additional practical applications of the latter subject.

Mr. Concordia suggests the applicability of matric methods to systems involving moments and products of inertia. It should perhaps be explained that a tensor is a matrix whose elements are differential operators.

Correspondence has also been received from Messrs. Collar and Duncan,[6] the originators of the method. It is stated that no special methods are required for the case of equal roots. Two sets of initial amplitudes will then give two different modes of the same frequency. Physical motions may then consist of any linear combination of these modes. A forthcoming book, "Elementary Matrices," by R. A. Frazer, W. J. Duncan, and A. R. Collar, Cambridge University Press, England, deals fairly exhaustively with the applications of matrices to dynamics and differential equations. These writers have independently found the property noted in Equation [10] of the author's paper, and give a shorter proof of it. They also bear out the statement at the end of part 3 of the paper, that high accuracy is necessary if several modes of a problem are to be found.

Heat Dissipation Through Annular Disk or Fin of Uniform Thickness[1]

Sam P. Soling.[2] This paper presents a good solution to the problem of the use of extended surfaces for heat transfer. The application of the results by the use of the base area of the fin and n, the "fin effectiveness," is rather unusual, not presenting as clear a picture of fin performance as might be obtained otherwise.

In many cases involving the use of finned surface, most of the external surface is extended surface and not primary surface. A factor to be applied to the usual heat-transfer equation involving surface coefficient, external surface area, and temperature difference is preferable, as it would never be greater than unity and would readily indicate the effectiveness of an extended surface. A copper fin might give a 90 per cent effective surface while, for an identical steel fin under the same conditions, the effectiveness would be but 60 per cent.

This factor, which may be designated by X, can be obtained by dividing n by the ratio of the fin surface area to the fin base area,

or
$$X = \frac{n}{\dfrac{R^2 - r_0^2}{2r_0 y}} = \frac{2\,r_0}{R^2 - r_0^2}\,\frac{\xi}{m}$$

In the example that the author has given, the fin effectiveness is 26.8, while the ratio of the fin surface to the fin base is 26.7, making X equal to 1.006. It is apparent that X should be slightly less than 1.0. The discrepancy is due to the difficulty of reading ξ from Fig. 2.

It appears to the writer, that it is more valuable to know that fins applied as in the author's example are almost completely effective, rather than that a multiplier of 26.8 should be used for the fin base area.

The factor X has been used for some time for finned surfaces with approximate values computed from the equation for bar fins,[3] and its use as outlined has proved valuable.

The author's Fig. 2 would be more useful if the two variables mR and mr_0 were extended to include higher values of surface coefficients, of approximately 300 Btu per sq ft per deg per hr.

Author's Closure

As Mr. Soling has pointed out there are two methods for expressing the heat transfer from a fin. The first scheme, which has been in use here and in Europe for some time, makes the comparison by means of the fin efficiency, Mr. Soling's quantity X, which is the ratio of the actual heat transferred by the fin to the heat which would be transferred if the whole of the fin were at the temperature of the base. The fin efficiency provides a good means of comparing two different fins but gives no information as to the actual heat-transfer without recourse to the fin area.

The second method using the fin effectiveness eliminates the necessity for calculating the fin area and at the same time provides a means of comparison although the measuring stick is slightly different from that of fin efficiency. The method given in the paper was developed specially to eliminate the step of finding the fin area in the calculation of the total heat-transfer from a finned tube but it is apparent that the adoption of either method of computation depends largely upon personal choice and any special conditions which may be involved.

Book Reviews

Men of Mathematics

MEN OF MATHEMATICS. By E. T. Bell, Professor of Mathematics at the California Institute of Technology. Simon and Schuster, New York, 1937. Cloth, 6¼ × 9¼ in., xv and 592 pp., illustrated, $5.

REVIEWED BY A. NÁDAI[1]

THE well-known author of this book, past-president of the Mathematical Association of America, has endeavored to acquaint the nonmathematical reader with the principal achievements and with the short life stories of a few men who have been the founders of "the Queen of the Sciences" from ancient to present times. The reader of this book will first find singular quotations gathered on three pages from many of the finest mathematical as well as nonmathematical thinkers expressing their ideas concerning the purposes for which mathematics has been developed. For Kronecker, "God made the integers, all the rest is the work of man;" for the Pythagoreans, "number rules the universe;" for Plato, "God ever geometrizes;" for the great Jacobi, "God ever arithmetizes;" but the truest statement of all of them was perhaps made by an analyst and founder of new functions, "a mathematician who is not also something of a poet will never be a complete mathematician" (K. Weierstrass).

The intentions of the author in this remarkable book may have been inspired by another celebrated book, namely, "Great Men," by W. Ostwald, published some thirty years ago. While in Plutarch's still so fascinating comparative biographies the ancient ages with their partially fabulous achievements are reflected, our rational times find or search the scales for a comparison in other properties of the great men. Ostwald selected his great men exclusively from among the physicists and chemists of the nineteenth century. Ostwald saw in the founders of the exact sciences two distinct types of men, which he somewhat associated with the different temperaments distinguished already by the ancient writers and philosophers: The quickly reacting "romanticists," among whom he believes can be found the great inspirers of youth and the founders of new schools, and the second type, the phlegmatic and precise "classicists." Davy, and Liebig, were for Ostwald romanticists, while Faraday and Helmholtz were classicists for him.

This new book by Bell may be characterized by his own words, "the gist of the story is in the lives and personalities of the creators of modern mathematics," no schemes being advanced for their classification other than the fundamentality and originality of their accomplishments. In contrast to other biographers, Bell attempts to show "that a mathematician can be as human as anybody else." According to him the mathematicians as a group have been "vigorous, alert, keenly interested in many things outside mathematics," statements which it is hoped will contribute much to reverse current ideas still perhaps prevailing among educated men for whom mathematicians have been concentrations of dryness, abstraction, and absent-mindedness. Bell quotes that during the eighteenth and early nineteenth centuries quite a number were soldiers, for the reason that mathematics and mechanics were not yet separated from each other nor from military science. We would like to add that perhaps quite a number were also outstanding engineers. The list comprising some thirty names starts with a few early Greeks (Zeno and Archimedes) and ends with Henri Poincaré and Georg Cantor (1918). It is known that many proofs of an early age in mathematics (the Sumerian, Babylonian, and Egyptian) exist. But these times were excluded, and leaving the Greeks, the list jumps to the names of Descartes, Fermat, Pascal, Newton, Leibnitz, the Bernoulli family, Euler, Lagrange and others up to Weierstrass, Riemann, and Hermite. The book contains 30 portraits; the frontispiece is Albrecht Duerer's "Melancholia" with the winged genius absorbed in contemplation over the unsolved puzzles of nature, a large crystal block resting beside, and a rainbow appearing above, the seated genius in the sky. The author has admirably understood how to paint with a few strokes the personalities he has selected. His essays do not tire the reader with scholarly details. He must have studied them and their works most carefully. He discloses, for example, quite a remarkable knowledge of prewar conditions and of life in academic circles in Europe and lifts the veil from circumstances under which appointments were made, which have subsequently influenced the lives of the great as well as the less great. One of the most thrilling life stories is perhaps that of the unfortunate Galois, "an all-time record in stupidity" of circumstances adverse to genius, combined with the absent-mindedness of influential contemporary authorities and ending at 21 years of age in a duel. Under "Master and Pupil" the author describes the personalities of the "father of modern analysis," of the unselfish, helpful, broad-minded Weierstrass and that of his brilliant pupil, Sonja Kovalevski. May one not be tempted to admit, when recalling his belief, that pure mathematics is perhaps the art of creation of entirely new forms for exact expression and of new harmonies between functional relations, that the boundaries between the arts and the exact sciences have, after all, been drawn too artificially and that a great worker in the purest of all sciences has much in common with a creator of music, or a sculptor of forms.

The Scientist in Action

THE SCIENTIST IN ACTION. By William H. George, Royal Society Sorby Research Fellow, and Honorary Lecturer in Physics, University of Sheffield. Williams and Norgate Ltd., London, 1936. Cloth, 5½ × 8¼ in., 355 pp., 31 figs., 10s 6d.

REVIEWED BY C. RICHARD SODERBERG[2]

THIS book cannot be classified as easy or entertaining; it commends itself to the reader chiefly through the immense significance of the subject to the welfare of our civilization. The author's purpose is to classify the processes whereby the scientific worker achieves his results. To this end he analyzes in separate sections "The Scientific Outlook," "Getting Scientific Facts," and "Arranging Scientific Facts."

The author professes "an uncompromisingly nonphilosophical point of view" and treats scientific research simply as "a problem in human action." In the opinion of this reviewer, this limitation is to be regretted, and may be one of the reasons for a certain dryness and tediousness of presentation, which makes for hard reading. This is particularly true of the first two sections.

The last section, occupying practically one half of the book, is by far the most interesting and readable. Some of the quota-

[2] Mechanical Engineering Department, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

tions from scientific writers help to relieve the monotony. Edmund Gosse's "Father and Son" provides an illuminating example of the processes by which the six-year-old son applied the experimental technique to the efficacy of prayer. He felt a need for a large humming top, a need that impressed him as much more real than the conversion of the heathen, or the restitution of Jerusalem to the Jews. When the father forbade him to pray for things like expensive humming tops, he reached the fatal suspicion that the whole objection lay in the fact that the humming top was too expensive to buy. The famous sentence "I determined, however, to test the matter for myself" was related to the injunction against idolatry. This he subjected to an experimental test with completely negative results. His interpretation of this result left his belief in the existence and power of God intact; it merely convinced him that his father was not really acquainted with the divine practice of idolatry.

There is one important aspect of the human mind which for some reason has been given very little emphasis. This is the intuitive process, or the influence of unconscious behavior upon scientific work. Whatever the ultimate scientific explanation of the intuitive process, it cannot be denied that it has played an important rôle in the final formulation of many discoveries and inventions. This omission may be justified by the author's nonphilosophical point of view, but it has eliminated much that is valuable and pertinent. Planck's statement that "creative minds have felt a personal aversion from the idea of unfolding before the public gaze those delicate threads of thought out of which their productive hypotheses were woven, and the myriad other threads which failed to be interwoven into any final pattern" is interpreted as a reluctance of great scientists "to give in public detailed account of their failures." This appears somewhat unfair. Is it not equally true that the great minds usually have been unable to give a detailed account of the mental processes by which they reached their discoveries? All scientific discoveries have been preceded by long hours of concentrated conscious activities, out of which intuitive flashes were precipitated.

Experimental research, particularly in our industries, requires one setting which money alone cannot buy. This is a body of capable research workers animated by enthusiasm for their work and by zeal for opening up new perspectives in their field. No one has yet explained just what the premises are for this, but one of the essential elements is probably some one man with the gift of leadership. Once this condition has been realized, something very precious has been created, something which is easily lost if adequate moral and financial support is withheld. Few institutions are thus endowed more than once in their history. Industrial research furnishes many examples where this rare setting has been brought about without full realization of its potential value on the part of the financial leaders. Lack of support to an institution of this kind means unpredictable losses in scientific and technical advance; any amount of support to an institution lacking in this setting usually means wasted expenditures.

A better understanding of the mental processes by which great men arrive at their discoveries will probably not enable lesser minds to produce great thoughts. If the world at large could be persuaded to value the veneration for truth, and more particularly, the disdain for Absolute Truth, which has always been the prerogative of great minds in the world of science, some hope could be held out for the eventual solution of our social problems. While the author disclaims any such purpose he has, nevertheless, succeeded well in demonstrating that the most precious contribution of men of science to the world is just the ability to accept truth regardless of whether or not it coincides with preconceived notions.

Physics

RECOLLECTIONS AND REFLECTIONS. Sir J. J. Thomson, O.M., D.Sc., F.R.S., etc. Master of Trinity College, Cambridge. The Macmillan Company, New York, 1937. Cloth, 6 × 9¼ in., viii and 451 pp., illustrated, $4.

THE NEWER ALCHEMY. By Lord Rutherford, O.M., F.R.S., Cavendish Professor of Experimental Physics in the University of Cambridge. Cambridge University Press. The Macmillan Company, New York, 1936. Cloth, 5 × 7½ in., viii and 67 pp., xiii plates, $1.50

REVIEWED BY J. C. BOYCE[3]

FEW, if any, university professorships can claim as distinguished incumbents as the Cavendish Professorship of Experimental Physics in the University of Cambridge. The chair, created in 1871, was held by James Clerk Maxwell until his death in 1879. Following the five-year term of Lord Rayleigh, J. J. Thomson was elected in 1884 and retired in 1919. Lord Rutherford, the fourth Cavendish Professor, maintained until his untimely death on October 19, 1937, the high traditions established by his illustrious predecessors.

J. J. Thomson entered Cambridge as an undergraduate in Maxwell's time and has resided there ever since as research student, fellow, professor, and then as Master of Trinity College. "Recollections and Reflections" deals far more with the scientific and academic life of that whole period than it does with the personal achievements of its author. In that sense it is a very modest autobiography, and yet delightful personal glimpses are scattered through it. Most of the previous generation of British physicists were Thomson's colleagues or friends; many of the present generation were numbered among his students. In 1895 the University began to offer its degree for research to graduates of other universities. From then on a considerable number of students from abroad were to be found every year in the Cavendish Laboratory, coming largely but by no means entirely from the British Empire and from the United States. Apropos of this Thomson writes, "The advantage gained by our own students by their intercourse with men of widely different training and experience, of different points of view on political, social, and scientific questions, of very different temperaments, can, I think, hardly be overestimated."

Strictly scientific matters are reserved for the last quarter of the book. In the earlier portions glimpses are given of many scientists and men of affairs, Maxwell, Rayleigh, Stokes, Kelvin, Crookes, Arthur Balfour, Woodrow Wilson, to mention a few. Readers of this journal will be particularly interested in the account of Dr. Routh, who influenced so greatly the teaching of analytical statics and of rigid dynamics. Thomson made three visits to the United States, in 1896, 1903, and 1923. He comments on the development of American universities during that period as well as on aspects of student life here. Thomson looked into the matter of psychical research and devotes a brief chapter to his quite unconvincing (to him as well) experiences.

The strictly scientific portion of the book gives an elementary account of some of Thomson's researches, including those related to the conduction of electricity in gases and the discovery of the electron.

The title of the work is an accurate one. It is pleasant to note that Thomson's life has been full of interesting people and interesting problems. "I owe to the Laboratory not merely the opportunities it has given me for indulging my scientific tastes in a way that would not have been possible in any other place. I owe to it besides many valued friends, and memories of friendships which can no longer be more than memories."

Turning from these "Recollections and Reflections" we find in

[3] Assistant Professor of Physics, Massachusetts Institute of Technology, Cambridge, Mass.

Rutherford's "The Newer Alchemy" a brief, nonmathematical and extremely lucid survey of the present state of knowledge of the nuclei of atoms and of transmutation. It may be read with interest by anyone having an elementary knowledge of physics and chemistry, yet to experts it speaks with the authority of the greatest master of the subject.

Reviewing the properties of radium and of the other radioactive substances, Rutherford describes the various elementary particles which take part in transmutation experiments—the alpha particle, proton, neutron, deuteron, and negative and positive electrons. Even the most severe critic must approve of the omission of that recondite particle, the neutrino, from a book of this scope. Methods of detecting individual particles are described, particularly that most spectacular one due to C. T. R. Wilson in which the track of the individual particle is made visible by water drops condensed on the ions formed along its path. Photographs of such tracks appear in illustration of several transmutations. In 1919 Rutherford found evidence that alpha particles directed against nitrogen could transmute a few of the nitrogen atoms into oxygen. Here then was the first true controlled transmutation, but a most expensive and inefficient alchemy it was, for only one alpha particle out of about 50,000 scored an effective hit. Further experiments with alpha particles produced transmutations among other light elements and led to the discovery of the neutron by Chadwick in 1932 and of artificial radioactivity by Irene Curie and F. Joliot in 1933.

The practice of this alchemy was limited by the available supply of radium as a source of alpha particles. Rutherford describes the electrical methods (including the cyclotron of E. O. Lawrence and the electrostatic generator of Van de Graaff) by which ions of hydrogen or of helium may be given more energy than the alpha particles from radium, and may be supplied far more copiously and conveniently. Rutherford describes some of the transmutations effected by these methods on the larger (but still tiny) scale. In conclusion he disposes of two familiar fallacies. Gold indeed may be produced by this alchemy, but from platinum rather than from lead (and at a cost far greater than the cost of the platinum). Large quantities of energy are produced by individual atomic encounters, but the occurrence of such successful hits is so rare among the many bombarding projectiles that "there is little hope of gaining useful energy from atoms by this process."

Science and Human Experience

SCIENCE AND HUMAN EXPERIENCE. By Herbert Dingle, Assistant Professor of Astrophysics, Imperial College of Science and Technology, South Kensington. First edition. The Macmillan Company, New York, 1932. Cloth, $5^1/_2 \times 8^3/_4$ in., 136 pp., $1.75.

REVIEWED BY J. ORMONDROYD[4]

NOTHING is more amusing and diverting than paradox. The popular writers on modern science have reveled in the paradoxical contrast between the pedestrian findings of classical physics and the more startling results of recent years. Jeans and Eddington instantly come to mind as the leaders of this activity. They have diverted the world so successfully that wealth and honors have been showered upon them. But it is no exaggeration to state, on sober reflection, that their attempts at explanation have ended in bewildering the reader. They have convinced their public that science in its modern form is completely unintelligible and apparently lacking in sense.

There have been inevitable reactions to this stressing of paradox and surprise. It is significant that the philosophical writings of the modern masters of physics—Planck, Bohr, Einstein, and Bertrand Russell—have always, during this period, been nearer to the common man's outlook. But their works, because they are more sober, come less to the attention of everyday readers.

Among the recent works which attempt to bring modern scientific activity within the understanding of the ordinary educated man, at least four should be mentioned. "Science and Human Experience" by Herbert Dingle, which appeared in 1932, "Through Science to Philosophy" by the same author published in 1937, "The Renaissance of Physics" by Karl Darrow, 1937, and "The Evolution of Physics" by Einstein and Infeld, 1938. All of these essays are healthy antidotes against the sensational mysticism so widespread in this field.

Our review concerns the oldest of these publications, "Science and Human Experience" by Herbert Dingle. In a certain sense Professor Dingle considers this older work superseded by his later book, "Through Science to Philosophy." But this book, which is longer and more abstruse than the older volume, still only reemphasizes the attempt at intelligibility started in the earlier, simpler discussion. Professor Dingle, a man widely versed in modern science, is not rated among the brilliant physicists and philosophers of our time. In fact, he identifies himself with the ordinary mortal who is disturbed and dissatisfied with the confused picture of modern science drawn in the great mass of current popular scientific literature. For these very reasons he possesses the qualities necessary to give an interpretation more satisfying to the intelligent layman.

Dingle defines science as "the recording, augmentation, and rational correlation of those elements of our experience which are actually or potentially common to all normal people." The entire content of "Science and Human Experience" consists in the development of this text. The source of all our usual confusion, according to Dingle, lies in the supposed contrast and interaction between "subject and object," between sensations and a real, external world. But "real, external world" and "object" have no meaning to Dingle. The true contrast is between experience (remembered sensation) and reason—both completely resident in the subject. The chief activity of science lies in the attempt of reason to correlate experience, that is, to bring the description of experiences to the simplest and most orderly form, based on the fewest possible elements. Anything which makes correlation possible is permissible, whether it take the form of mechanical models—which can be imagined to have possible physical counterparts—or purely mental concepts which have no prototype in familiar surroundings. The search for correlation is something entirely different from a search for "reality." If we insist on tying our understanding of modern science to some criterion of everyday "reality," we are doomed to confusion and intellectual despair. The train of successful scientific thought starts from observation—permits itself the widest latitude of abstraction and hypothesis—and ends up with an accurate description of the observation. This is the only reality we must demand of science. This is the reality Dingle demands.

The strangest thing about this defense of modern science is that it is exactly the defense which classical science needed. The apologist who wrote the preface to "The Revolution of the Heavenly Bodies" by Copernicus used the very same argument as long ago as 1543.

The correlating devices consist of abstraction and hypotheses. Hypotheses are classified by Dingle into three kinds: Hypotheses which can be and are checked (becoming thereby "facts"); hypotheses which cannot be checked since the conditions assumed in them do not exist within the reach of observation, such as the nebular hypothesis; and hypotheses which by their very nature can never be checked, such as the atomic hypothesis.

[4] Professor of Engineering Mechanics, University of Michigan, Ann Arbor. Mem. A.S.M.E.

These last Dingle christens "correlates." All three are admissible and useful in the business of science—which is the correlation of experience.

The theory of relativity represents the extremity of abstraction and the quantum theory is the extremity of hypothesis. "The apparent absurdity of Relativity is entirely a matter of limited experience, and that of the quantum theory is entirely a matter of limited thought. Relativity teaches us about phenomena because the notions it deals with are abstracted from our experience of phenomena; it surprises us because it reveals possibilities of experience which we never contemplated. The quantum theory surprises us because it reveals *impossibilities* of experience which we never contemplated; we thought we were justified in extending to atoms the abstractions discussed in relativity, and we find that we were not."

The meat of this work is contained in the first 102 pages. Chapters 10 and 11 discuss "Science and Criticism" (of Art) and "Science and Religion." They do not add anything worth-while to the viewpoint developed in the work.

It is indeed unfortunate that Dingle will never reach the audience that his more acrobatic competitors have charmed. A little bit of Jeans and Eddington should always be followed by large doses of Dingle. However, the poison is served in large doses and the antidote comes in a very small package.

Theory of Statically Indeterminate Structures

THEORY OF STATICALLY INDETERMINATE STRUCTURES. By Walter Maxwell Fife, Associate Professor, and John Benson Wilbur, Associate Professor, Department of Civil Engineering, Massachusetts Institute of Technology. First edition. McGraw-Hill Book Company, Inc., New York, 1937. Cloth, 6 × 9¼ in., ix and 248 pp., figs., $3.50.

REVIEWED BY J. M. GARRELTS[5]

THIS TREATISE possesses a superior technique in its clear and thorough development of principles of structural mechanics. The authors have stressed the importance of the so-called classic methods of analysis on the basis that they are essential to an understanding of structural action. Those familiar with the theory of statically indeterminate structures will generally agree with this viewpoint.

In the first chapter, fundamental assumptions involved and consequent limitations of the theory are carefully considered. Requirements for structural stability and the conditions for equilibrium of statically indeterminate structures are well presented. The equations for virtual work are evolved from a consideration of the virtual work of distortion produced during virtual deformation of an element under the action of given stress intensities. The development of the equations in a general form to include the effects of bending, direct stress, temperature differences, and shear is a splendid demonstration suggesting the power of the virtual-work principle as a tool in structural analysis. Application is made of the law of virtual work as an expedient for determining the displacement of any point in a distorted structure. The bar-chain method for computing deflections of the joints of a truss is clearly explained and a number of examples illustrate the principle. The moment-area theorems and the conjugate-beam method are adequately demonstrated.

The chapter on stress analysis for statically indeterminate structures is outstanding for its clearness of presentation. The law of virtual work and Castigliano's theorem are applied to the analysis of statically indeterminate trussed structures and redundant frames with moment-resisting joints. Simplifications resulting from the use of the elastic center are discussed. The development of the slope-deflection equations is concise and should be readily followed by the student. The necessary free-body diagrams for determining equations of equilibrium are included with the problems illustrating the application of these equations. The principle of moment distribution for determining the stresses in structures with moment-resisting joints is developed from slope-deflection equations.

Of particular interest is the chapter on influence lines for analyzing the structural effect of variable load conditions. The elastic curve and Maxwell's law are used to construct influence lines for deflections, stresses in redundant truss members, and redundant reactions. The conception of a statically indeterminate primary structure is discussed as a basis of mechanical methods of analysis, and its advantages in drawing influence lines are considered. In constructing influence lines for continuous beams of several spans, the fixed-point method illustrated is an aid in solving the three-moment equations.

In considering secondary stresses in trusses, approximate analyses for determining these secondary effects are presented and the correlation of primary and secondary stresses discussed. The methods of Manderla, Mohr semigraphic and moment distribution are treated. Under the heading of "Participating Stresses," the authors have properly called attention to a problem that may require consideration in a bridge design.

The solution of many illustrative problems in the text facilitates application of the theory to practical problems, while a number of problems for solution by the student are included following the text material.

This book warrants careful study by those interested in the theory of statically indeterminate structures. The clarity of development and presentation is stimulating and the thoroughness with which fundamental principles are demonstrated is gratifying.

Statically Indeterminate Frameworks

STATICALLY INDETERMINATE FRAMEWORKS. Thomas F. Hickerson, Professor of Civil Engineering, University of North Carolina. The University of North Carolina Press, 1937. Cloth, 8½ × 11 in., xi and 205 pp., figs. and tables, $3.

REVIEWED BY JOHN B. WILBUR[6]

"STATICALLY Indeterminate Frameworks," is a revision of Professor Hickerson's previous volume, "Structural Frameworks." In addition to a complete revision of the former text, the new volume has been extended to deal with statically indeterminate frames.

The tremendous impact of "moment distribution" on the field of structural thought is clearly in evidence in Professor Hickerson's treatment of the subject. Starting with a consideration of restraint, continuity, and stiffness, the author discusses the slope-deflection theorem, and from this as a base, develops the method of moment distribution. His treatment of this method is unusually complete. Applications to structures of many types are considered, with special emphasis on building frames and rigid-frame bridges. Many tables are given which greatly reduce the labor involved in the procedures suggested.

As a treatment of new methods of applying basic theory, this book should be of value not only to students, but to designers as well. The writer is of the opinion, however, that if the volume were intended to be a complete treatment of statically indeterminate frameworks, more discussion of the so-called "classical"

[6] Associate Professor of Civil Engineering, Massachusetts Institute of Technology, Cambridge, Mass.

methods of stress analysis for statically indeterminate structures would have been in order. The method of moment distribution is essentially a technique of solution, rather than a method based on principles which are fundamentally new. It seems to the writer that this volume tends to accent the "how" of stress analysis, rather than the "why," and the question is raised in his mind as to whether the searching student of structures may not feel the need of further and more basic treatment of the subject.

Theory of Modern Steel Structures

THEORY OF MODERN STEEL STRUCTURES. By Linton E. Grinter, Ph.D., C.E., Professor of Structural Engineering, Agricultural and Mechanical College of Texas. The Macmillan Company, New York, 1936. Volume 1, fabrikoid, 6 × 9 in., xxv and 317 pp., illustrated, $4; Volume 2, xvii and 285 pp., illustrated, $4.50.

REVIEWED BY L. C. MAUGH[7]

IN MAKING a review of two volumes that treat of so comprehensive a subject as the theory of modern steel structures, the reviewer immediately encounters difficulty in discussing the relative importance of the selected subject matter and its arrangement in a limited amount of space. To make the discussion as definite as possible, the two volumes will be treated separately.

Volume 1 is restricted to the analysis of determinate structures although this classification is, in many instances, based more upon the assumptions that are made for purposes of analysis than upon the physical characteristics of the structures. The first chapter provides an interesting summary of the historical development of the various types of present steel structures, following which a well-illustrated and clearly described chapter on the fundamentals of stress analysis is given. Both graphical and algebraic methods of determining reactions and internal stresses are presented as well as shear and bending-moment diagrams for stationary loads.

The application of theory of stress analysis to mill buildings, highway and railway-truss bridges, plate girders, and tall steel buildings is presented in subsequent chapters. The material on truss bridges, although following the usual arrangement, is exceptionally complete and well illustrated. It is in the chapter on tall-building frames that the most noticeable differences from current textbooks are found. Here we find a discussion of structural arrangement of beams and columns, of analysis for wind stresses based on approximate methods, of the use of brackets and knee braces, and the advantages of various types of connections. These practical descriptions and illustrations should be helpful both to the beginner and to the more experienced designer. It seems that some discussion of space structures could well be placed in the first volume rather than the second. In general the subject matter of the entire first volume is so well illustrated by free-body diagrams and photographs that acquiring a working knowledge of the fundamental concepts of structural theory should be a pleasant task to any interested reader.

In the second volume, which is primarily concerned with the analysis of statically indeterminate structures, there are the same clear descriptions and excellent use of illustrations that characterize the first volume but the choice of subject matter is more open to question. After a general discussion of indeterminate structures, a chapter on the analysis of space structures such as towers, pedestals, and framed domes is given. Only space structures of a determinate type are considered. The next chapter considers the deflection of beams and trusses by various methods such as virtual work, Castigliano's theorem, area moments, and method of elastic weights. As the reader is expected to have had some of the mathematical development of these principles in courses in strength of materials, the text is largely confined to a statement of the fundamental concepts involved and their application to engineering problems. Although this description is undoubtedly sufficient for area moments and the method of elastic weights, the use of the strain-energy methods and the reciprocal theorem could well be given a more extensive treatment. Also, the slope-deflection method would be more useful if developed from the general case for members with variable cross section rather than for constant cross section only.

The analysis of continuous beams and trusses by various methods is then considered, following which a short description of movable, cantilever, arch, and suspension bridges is given. The subject of continuous frames receives considerable attention in the remaining portion of the second volume, principally by a study of the effect of the rotational and linear displacements of the joints. In this analysis, the use of the moment-distribution method in determining the effect of joint rotation, of restraining forces to control translation, together with the general rule of superposition, are all emphasized and illustrated. The subject of arches and rings is treated by both the neutral-point (elastic-center) and column analogy methods. The latter is accorded an unusually comprehensive treatment.

A closing chapter on the analysis of continuous frames by balancing angle changes, a method originally introduced by the author, is presented. Even though this discussion enables some consideration to be given to the effect of semirigid connections, a more extensive treatment of this problem might well be made. In general, a study of the many procedures that are discussed by the author for the analysis of continuous frames gives rise to a feeling that perhaps too many tools are placed before the reader before he is sufficiently familiar with the fundamental concepts. The final result will, of course, depend upon the experience of the reader.

Principles of Powder Metallurgy

PRINCIPLES OF POWDER METALLURGY. By W. D. Jones, M.E., Ph.D. Lecturer in Metallurgy, Sir John Cass Technical Institute. Longmans, Green & Co., New York, 1937. Cloth, 5½ × 8½ in., xii and 199 pp., 73 figs., $5.

REVIEWED BY S. L. HOYT[8]

"POWDER Metallurgy" by W. D. Jones, "the first work in English on this subject," was opened by your reviewer with more than the usual interest in a new book. The field covered, though limited, has rich possibilities for a fine scientific treatment and interesting technical applications are in daily practice. Many workers in all parts of the world are engaged in this new branch of metallurgy and your reviewer was curious to learn how they were treated by their first "text" in English. It is with real gratification that he can report that the author has written his book with rare skill and fine judgment. This has obviously been a labor of love and we are fortunate that it was one of Dr. Jones's ability who set himself the task.

The scope of the subject matter is adequate. By chapters the book treats of principles of sintering and massive metals; principles of sintering and comminuted metals; physical properties of sintered metals; industrial applications; manufacture of hard metal alloys by sintering; manufacture, properties, and testing of metal powders, in all, 189 pages. Numerous illustrations and sketches are given of equipment and products. The author has gone to great pains in his discussion of the many points that arise

[8] Director of Metallurgical Research, A. O. Smith Corporation, Milwaukee, Wisconsin.

and records the results of numerous scientific investigations for quantitative treatment. The general metallurgist will doubtless be surprised at the extent and content of the subject matter though it will be the specialist who will really profit by a careful reading. Even in this special field of metallurgy there are specialties and here we find them all carefully and thoroughly discussed.

In view of the excellence of this book, the reviewer hesitates to interject adverse criticism. However, it was only the discussion of tungsten that was found to be inadequate and below the standard of the book as a whole. In view of the large body of competent opinion in this particular field, it is perhaps unfortunate that care was not exercised to make this part one of the strongest. It is only fair to say that the author refers to the well-known text of Smithells for a discussion in English of the subject. Of a different character is the criticism that no attempt is made to acquaint the reader with the names and work of many of those who were responsible for the present position of powder metallurgy; instead the author utilizes sources which are best suited to scientific or technical discussions and they are generally of recent date. With a little additional effort the historical development could have been given. Finally the author appears not to be acquainted with the interesting copper-tungsten electrode material known as Elkonite.

This book is to be highly recommended and for all those engaged in the study or practice of powder metallurgy it rates first place as "must" reading.

Heat and Thermodynamics

HEAT AND THERMODYNAMICS. By Mark W. Zemansky. First edition. McGraw-Hill Book Company, Inc., New York, 1937. Cloth, 6 × 9¼ in., xii and 388 pp., 101 figs., $4.

REVIEWED BY JOSEPH H. KEENAN[9]

THERE IS little in the literature of thermodynamics that serves as a guide from first steps to the place where Gibbs begins. Professor Zemansky in his book "Heat and Thermodynamics" has made a creditable effort to strengthen our elementary literature. He does not attempt to cover all the thermodynamic analysis that one encounters in current literature; but he does cover the ground leading up to Gibbs.

Many engineers would not classify this book as engineering thermodynamics. There can be little argument, however, that all but a few of its 388 pages could be classed as thermodynamics the engineer should know.

From the preface we learn that "The first ten chapters deal with the fundamental ideas of heat, reversibility, entropy, etc., in a manner which strives at a compromise between rigor and simplicity;" and that "An attempt has been made to reduce the number of occasions in which the student is asked to refer back to a previous equation." Both these objectives have been attained to an unusual degree. The material is attractively presented and easy to read. Concerning kinetic theory and thermodynamics we read "The author believes that the study of molecular physics embodied in statistical mechanics and kinetic theory should not run parallel with but should follow a course in thermodynamics, in order that the power and limitations of the macroscopic point of view may be clearly understood and not confused with those of the microscopic point of view." Among his references he makes particular mention of the texts by Roberts, Planck, Lewis and Randall, and Kiefer and Stuart.

The book opens appropriately with a thoughtful and detailed discussion of temperature and its measurement. A chapter entitled "Work" includes the usual discussion of change of volume against a pressure, but is general enough to comprise work corresponding to change of length against a tension, change of area against a surface tension, change of charge against an electromotive force, and change of magnetization against a magnetic field.

The chapter entitled "Heat" adequately defines heat and describes its measurement. The 15-degree calorie is chosen and accounts given of several measurements of its mechanical and electrical equivalents, though the latest measurements by Osborne are not mentioned. It is unfortunate that the only calorie on which there is unanimity as to definition and magnitude, the international-steam-table calorie, is not mentioned. The rest of the chapter on heat is made up of a discussion of heat transfer and of the measurement of heat capacity.

The second law is adequately introduced and is stated essentially in the words of Planck. The chapter on "Reversibility and Irreversibility," which follows that on the "Second Law," is good. It is to be regretted, however, that the author chooses to follow the precedent of Clausius by introducing "the universe" into his reasoning. For example, he says, "a reversible process is one that is performed in such a way that, at the conclusion of the process, both the system and the local surroundings may be restored to their initial states, without producing any changes in the rest of the universe." Only an omnispective scientist or engineer could apply this definition as stated; but even he would doubtless find that for experimental purposes an isolated system is less cumbersome than the universe.

In the chapter on "Entropy" there is a good discussion of "energy that is rendered unavailable for work" in an irreversible process. Though this item was probably inspired by engineering texts, it is a comfort to find that the author has not accepted the usual treatment of unavailable energy which requires for its validity many interpretations and reservations which are almost never expressed.

Two chapters entitled "Applications of Thermodynamics" comprise a collection of illustrative cases that are not especially difficult. Most of them are of interest to the engineer. There are chapters of intermediate difficulty on "Change of Phase" and "Mixtures of Inert Ideal Gases." More advanced chapters deal with "Chemical Thermodynamics," "Ideal Gas Reactions," and "Heterogeneous Systems." In these the author follows the method of Gibbs in treating of equilibrium and equilibrium constants, the phase rule, the effect of pressure on vapor pressure, etc.

The illustrations are good—particularly those in the chapter on "Properties of Pure Substances." The problems which follow each chapter are the product of imagination and originality. Nowhere in the book is the diligence of the author more evident.

Despite the good quality of the work as a whole, a long list of defects, major and minor, might be prepared. The weakest member in the author's structure is doubtless the chapter on the "First Law." Surely it is meaningless to say "The principle of conservation of energy applied to a thermodynamic system and its surroundings is called the first law of thermodynamics" unless the term *energy* is defined. It is futile to expect the student to draw upon sciences previously studied for the definition, because none of them provides a general definition. In fact, no general definition of energy existed until the first law was enunciated.

The first section of this chapter is devoted to the subject of internal energy, which it defines quantitatively only by the remotest implication. The real definition appears in an equation at the end of the chapter. In view of that definition a casual statement at the bottom of the second page of the chapter is an adequate statement of the first law.

In a treatise as general as this one there is much to be gained by following Gibbs in permitting the term *internal energy* to in-

[9] Associate Professor of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

clude kinetic energy and potential energy of all kinds. A loss of simplicity and a multiplication of terms results from the author's method of reserving the term *internal energy* to a system in the simplest kind of state.

We may be glad that a book has been written which is devoted to the task of developing a sound elementary exposition of thermodynamics, and which applies to that task an unusual amount of skill and imagination.

Statically Indeterminate Stresses

STATICALLY INDETERMINATE STRESSES. By John Ira Parcel, Professor of Structural Engineering, University of Minnesota, and George Alfred Maney, Professor of Structural Engineering, Northwestern University. Second revised edition. John Wiley & Sons, Inc., New York, 1936. Cloth, 6 × 9¼ in., xvi and 432 pp., 200 figs., $5.

REVIEWED BY L. C. MAUGH[10]

IN THIS revision of a text and reference book that has given valuable service during the last twelve years, the authors have naturally retained the essential features and basic principles of the first edition. Although several changes in the arrangement of the original text have been made, the essential difference is embodied in the addition of the moment-distribution method for the analysis of frames and of a chapter on suspension bridges.

A chapter on methods of calculating the deflection of structures provides the necessary tools for the solution of the various problems that are treated in the subsequent chapters. The Maxwell-Mohr or unit-load method, Castigliano's theorem, moment area, method of elastic weights, and Williot-Mohr diagrams are all explained and illustrated. The relative merits of the various methods are discussed, particularly the type of problems for which each is best adapted.

In the following chapters on the calculation of stresses in continuous beams and indeterminate frame structures, the use of the unit-load method, moment area, and method of elastic weights together with Maxwell's reciprocal theorem is given particular attention. The slope-deflection method has been made the basic method for the analysis of rigid-frame structures and for the calculation of secondary stresses in trusses. The generalized slope-deflection equations for members with variable cross section are considered and a procedure for determining the necessary coefficients is given. In the problem of calculating the coefficients, it is doubtful if the generalized solutions that are given are necessary, as the statement of the solution together with a numerical example should suffice. The moment-distribution method is also used for the analysis of rigid frames although in general the space devoted to the use of successive approximations seems somewhat brief. The physical principles of the problem are clearly defined, but the writer believes that a more comprehensive treatment of the slope-deflection concepts that are involved in the moment-distribution method is necessary for the average reader.

The analysis of the ordinary elastic arch rib and arch truss is fully described and illustrated by numerical examples. The treatment is limited to arches with two-hinge and fixed supports.

An important addition to the new volume is a chapter on suspension bridges. This treatment considers both the approximate and the deflection methods, and each has been made sufficiently complete to give the average reader an excellent picture of the numerical calculations that are necessary for the ordinary types of suspension bridges. The physical principles that are involved and the assumptions that are necessary for analytical purposes are clearly described.

In general, the new edition treats those principles and methods that are necessary for the solution of the average problem in indeterminate structures. The large scope of problems that is considered in this treatment may be too comprehensive for the average course in structural theory, but, nevertheless, it is the material that should be made available for the student.

[10] Assistant Professor of Civil Engineering, University of Michigan.

Elasticity, Plasticity, and Structure of Matter

ELASTICITY, PLASTICITY, AND STRUCTURE OF MATTER. By R. Houwink, Plastics Department, N. V. Philips Gloeilampenfabrieken, Eindhoven, Holland. With a chapter on the Plasticity of Crystals by W. G. Burgers, Natuurkundig Laboratorium, N. V. Philips Gloeilampenfabrieken, Eindhoven, Holland. Cambridge University Press Department, The Macmillan Company, New York, 1937. Cloth, 5½ × 8¾ in., xviii and 376 pp., 214 figs., 40 tables, $6.

REVIEWED BY A. NÁDAI[11]

THE AIM of this book may be characterized by some statements quoted from the preface according to which the purpose was to bring "the physicist, chemist, and the technologist into a closer contact with each other, so that they may understand one another more easily." According to the author "unity of thought" is seldom encountered in the treatment of the properties of matter mentioned in the title of the book and "one of the tasks the author has set himself is the attempt to trace such a unity as far as this is at present possible."

He adds, however, that "the results of the contemplated comparison between the observations on the flow of such different materials as crystalline substances, glass, resins, asphalts, textile fibres, rubber, clay, sulphur, and others and some general laws, which are assumed to hold for deformation, are often disappointing." He hopes that progress will allow a "deliberate synthesis of materials with defined elastic and plastic properties." The trends in the manufacturing processes of metallic and of many other artificial materials recently developed seem indeed to confirm the author's hopes. It is known that mineral oils, asphalts, rubbers, etc., have been considerably improved, so that their mechanical properties can, to the advantage of the consumer, be predicted and guaranteed in advance.

In the first five chapters elastic and plastic deformation and questions of a structural nature are discussed in a general manner. One chapter contributed by W. G. Burgers summarizes the views concerning the mechanism of plasticity in crystals. The following chapters are devoted to the flow of special materials: Glass, resins, asphalts, rubber, cellulose, clay suspensions, etc. Under the heading "the yield value" some views are reproduced about the existence of a "tension at which flow becomes observable practically under the usual conditions of test." Against the phenomenological introduction of a "practical yield value" for the stress at which the plastic deformations start, not much need be said, although the way in which this was done may not be entirely satisfactory for a group of the prospective readers of the book, namely for the "technologists," i.e., engineers better acquainted with the laws of the yielding of ductile metals. However, when the author continues to state that "the existence of a practical yield value will be accepted as a possibility and in such cases we shall speak of solids;" and "if no practical yield value can be observed, the material will be called a fluid" (pp. 14 and 15) engineers will shake their heads.

[11] Consulting Engineer, Westinghouse Research Laboratories, East Pittsburgh, Pa. Mem. A.S.M.E.

A polycrystalline, ductile, annealed metal (copper and aluminum) at room temperature which starts to yield at the smallest stress should then belong to the "fluids," and a soft asphalt, if it happens to have a small "yield value," to the group of "solids." Not much seems to be gained by definitions of this nature when they are based on such a comparatively weak foundation. Is not the existence or nonexistence of a "yield value" dependent on many circumstances subject to gradual change, and on the order of magnitude of the speed of deformation, etc.? Whether a "yield value" has a significance or not is also entirely dependent on the temperature at which the "solid" is tested. Apart from such considerations, it should perhaps be mentioned that the term "yield value" is not used by mechanical engineers. In testing of metals, ever since steel has been used, the terms "yield point" or "yield stress" have long been in daily usage.

The efforts of the author of the present book in endeavoring to reach a more precise description of the flow of solids and to give a certain uniformity of expression should be commended. It seems, however, to the reviewer that if this were the purpose of the book the needs of a large group of readers interested in the flow of materials, namely, those of the engineers, should have been considered more. Because of the enormous variety of substances which can flow it might have been better to have separated entirely substances into two or three main groups (for example, into the metallic, the soft amorphous materials, such as glass, resins, etc., and the plastic clays, mixtures of solids with water), and develop the laws and the mechanics of flow for each group separately.

As far as the flow of ductile metals is concerned, this has been thoroughly investigated by engineers during many decades and at the end of the nineteenth century a number of good treatises already existed in which many important effects, including that of the speed of plastic deformation, etc., were clearly attacked. For the flow and the elastic deformation of the metals, definitions were in existence which were, and still are, entirely adequate.

In some recent publications in this country, a few definitions have been suggested for long-established and clearly defined material properties, which seem to be inadequate and which are also superfluous. The terms in mind refer to the three fundamental modes of deformation, namely, to the elastic strains, the plastic and the viscous flow of matter. When these are introduced in mechanics the best that can be proposed is to consider these three types of deformation *as important ideal cases for the possible modes of deformation and as abstractions for three of the most important types of existing distortion.* They are described fully in treatises on mechanics of continuously distributed substances, in the theories of elasticity, of plasticity, and of viscous substances. Furthermore an essential element in the mechanical treatment (for engineers at least) is the fact that stress and strain must be considered in three dimensions, on account of the many practical applications. Compared to these general theories the restriction to axial "tension" or "compression" would also limit the field to a considerable extent if engineering applications were to be considered. For these and other reasons it is felt that it would have been preferable to separate substances into the afore-mentioned main groups, perhaps excluding entirely the ductile metals from a treatment in which so many chemical and other viewpoints are important for the understanding of the flow of soft materials. For certain types of flow which, by the way, have a great significance for solid metals, in the book, terms such as "Newtonian" and "non-Newtonian" fluids are used. These seem rather forced combinations of names and words which could certainly be replaced by simpler terms.

It is to be hoped that these remarks do not obscure the considerable merits of the author, who has brought together, in a comparatively limited space, much valuable and recent information on flow. The book will be of value to all those who wish to find in a short time a maximum of reliable information with regard to the behavior of a number of very different materials, crystalline or amorphous. Considerable attention was given to include also in the book various chemical and structural questions.

Soil Mechanics

THEORIE DER SETZUNG VON TONSCHICHTEN. By K. v. Terzaghi and O. K. Fröhlich. Franz Deuticke, Leipzig and Wien, 1936. $6^1/_2 \times 9^1/_2$ in., 168 pp., 100 figs., bound, 14.40 rm, paper, 12 rm.

ERDBAUMECHANIK UND BAUPRAXIS, EINE KLARSTELLUNG. By K. v. Terzaghi and O. K. Frölich. Franz Deuticke, 1937. $6^1/_2 \times 9^1/_2$ in., 33 pp., 2 figs., 2 tables, 2 rm.

REVIEWED BY A. NÁDAI[12]

THE FIRST-mentioned book is the second issue in a series of elementary treatises to be devoted to the science of soil mechanics. The first issue on pressure distributions in the ground by Fröhlich has already been published and a third one by Terzaghi on the theory of earth pressure is in preparation. The well-known authority on soil mechanics, who has been teaching at Massachusetts Institute of Technology for a time, published in the present book jointly with Dr. Fröhlich an introductory volume containing the theoretical foundations for the treatment of the subsidence of the ground under buildings erected on soft-clay layers. Both authors have carried out with their collaborators during the past years many experimental investigations on the settling of foundations which are continued now in Professor Terzaghi's quite remarkable new laboratory on soil mechanics at the Technical University in Wien (Austria).

This book has perhaps also been written to replace certain portions of Terzaghi's "Erdbaumechanik" through which his new theory of soil pressures became better known several years ago. The physical properties of soft clay are discussed and variables introduced which make the former ones susceptible to an analytical treatment.

This leads to Terzaghi's well-known "thermodynamic analogy" of soil mechanics according to which a certain problem of the flow of water through soft-clay layers leads to the same differential equation, on which the theory of heat conduction through solids is based (Fourier's equation or the equation of diffusion). A number of simple solutions about the time-pressure distributions in such layers of clay are given, resting on pervious or impervious layers, in which cases a vertical flow of water is assumed. In later chapters cases are added in which the ground water penetrates from one side into the porous layer and leaves it in a horizontal direction on the other side. In the third chapter a number of exact solutions of Fourier's equation are discussed; the fourth chapter contains practical or numerical applications of the theory. This brief introduction to a soil mechanics of wet-clay layers needs no further recommendation to American readers; those who are probably not yet sufficiently acquainted or familiar with these attempts to introduce an exact treatment when dealing with these phenomena will welcome this clearly written book.

The second joint short monograph mentioned is more of the character of a pamphlet. It refers to a controversy on soil mechanics. Because of the death of the author of several articles, which started the controversy some time ago, it suffices to point out here that this pamphlet contains a refutation of the viewpoints expressed in these other articles.

Fluid Mechanics

AN INTRODUCTION TO FLUID MECHANICS. By Alex. H. Jameson, M.Sc. Emeritus Professor of Civil Engineering of London. Longmans, Green and Co., New York, 1937. Cloth, 5½ × 8¾ in., x and 239 pp., 116 figs., $2.50.

REVIEWED BY HUGH L. DRYDEN[13]

THIS book appears in response to the demand for a textbook for use in teaching fluid mechanics as a basic science of engineering. It deals with fundamentals, and numerous exercises for the student are included.

The author has chosen to omit all discussion of lifting surfaces, boundary layer, flow separation, turbulence except as it occurs in flow in pipes, lubrication, flow of compressible fluids except for a brief appendix, propellers, fans, and hydraulic machinery.

The book follows a carefully, thought-out logical plan; it first reviews the concept of pressure and the physical properties of fluids, treats the statics of fluids, derives Bernoulli's theorem from energy considerations, applies it to venturi meters and orifices, applies momentum and energy relations to impact of jets, and continues with the mechanics of fluids. Due consideration is given to dimensional reasoning and to model experiments. The author has succeeded admirably in his expressed aim of "illustrating the subject fully with diagrams, worked-out examples, and 'guided' exercises, and to keep it as free as possible from empirical formulae of tables of coefficients."

Two matters of terminology deserve comment. The author recognizes the common usage of the word "pressure" in the sense of total force and attempts to introduce the hyphenated expression "pressure-intensity" for the quantity usually designated pressure by most writers on fluid mechanics. The reviewer believes that it is preferable to teach prospective engineers to avoid the use of the word pressure in the sense of force and to reserve pressure for force per unit area. The author uses the words "boundary layer" for the region in a pipe which is usually designated "laminar sublayer."

The reviewer recognizes the difficulty of compressing the elements of an extensive subject within the allotted hours of a university course, but believes that the engineer should be introduced to the concept of pressure and velocity fields around objects immersed in fluids and within conduits and channels carrying fluids, and that some knowledge of the theory of lifting surfaces, of boundary layers, and of propellers, fans, and turbines is essential. Lubrication as such, and compressible fluids may perhaps be omitted. In view of the very concise manner in which the author has treated the subjects included, these additions could well be made in a subsequent edition without undue enlargement of the text.

Harmonic Analysis

RECHNERISCHE VERFAHREN ZUR HARMONISCHEN ANALYSE UND SYNTHESE. By A. Hussman. Julius Springer, Berlin, 1938. Cardboard, 8½ × 12½ in., 28 pages of text and 10 loose folding tables, 9.60 rm.

REVIEWED BY J. P. DEN HARTOG[14]

OF THE several methods for calculating the Fourier coefficients of a given periodic curve, the one devised by Runge is the simplest and most efficient. It consists of measuring a number of equidistant ordinates of the curve and performing a few simple addition and multiplication operations on them. Runge himself disclosed the general method and gave explicit tables for 12 and for 24 ordinates. The present book gives first a comprehensive discussion of various other methods of analysis, then goes into some detail on Runge's procedure, and gives explicit tables for 12, 24, 48, and 72 ordinates. With the latter 35 sine harmonics, 36 cosine harmonics, and the constant term of the Fourier series can be determined. The book is clearly written and the tables are easy to use.

The Theory and Performance of Axial-Flow Fans

THE THEORY AND PERFORMANCE OF AXIAL-FLOW FANS. By Curt Keller, Chief Engineer of Esher Wyss Laboratories, Zurich, Switzerland; adapted for the use of fan designers by Lionel S. Marks, Professor of Mechanical Engineering, Harvard University, with the assistance of John R. Weske, Assistant Professor of Aerodynamics, Case School of Applied Science. First edition. McGraw-Hill Book Company, Inc., New York, 1937. Cloth, 6 × 9 in., x and 140 pp., 36 tables, 112 figs., $4.

REVIEWED BY A. L. KIMBALL[15]

THIS IS the first book on axial-flow fans which has appeared in the English language wherein fan design is thoroughly treated from the standpoint of modern airfoil theory. The original of this book was in German by a well-known Swiss engineer.

The translators of this book are to be congratulated in making available information for which there has been a real need in this country.

It might indeed seem strange that modern airfoil theory was not sooner applied to fan design. The fact is that in some applications fans with blades of airfoil section have been disappointing. This was not the fault of the design but the result of misunderstanding as to how this type of fan should be applied.

A little consideration will make it clear that airplane propeller blades are designed for cases where the air flow through the blade area is almost entirely axial because of the high speed of motion of the plane itself. On the other hand, in most commercial fan applications the fan operates in air initially at rest which has to be greatly accelerated before it is delivered by the fan. As a result of this fact free-air propeller fans without guide vanes have to be designed to take account of the air inflow from all directions rather than for flow along the axis only. On the other hand if guide vanes are used so that the air is directed axially toward the fan blades a fine performance can be obtained from an airfoil type of fan. If the air is not properly directed in the front of the fan, however, its performance may be poor. It is for these reasons that no airfoil type of fan is really complete in itself alone. In fact, this volume discusses only cases where a fan is used with supplementary means of directing the air through the blade area.

Although the book contains 140 pages, it is made up of only four chapters.

In the first of these the basic theory is presented in which performance characteristics are given in terms of dimensionless constants.

The second chapter contains a study of fan losses in which it is shown how to design for maximum efficiency.

The third chapter presents the results of some wind-tunnel experimental studies of the performance of certain blade section profiles.

The fourth chapter gives the results which are of particular interest to most fan designers, i.e., actual performance data for four representative fans over a wide range of conditions, as determined from actual tests.

[13] Chief, Mechanics and Sound Division, Department of Commerce, Bureau of Standards, Washington, D. C. Mem. A.S.M.E.

[14] Associate Professor of Applied Mechanics, Harvard University, Cambridge, Mass. Mem. A.S.M.E.

[15] Engineering General Department, General Electric Company, Schenectady, N. Y. Mem. A.S.M.E.

A few words on how to interpret some of these data may be of value to those not having time to thoroughly study this book.

The results of the tables on pages 109 to 122 which give data from actual tests are set forth graphically in Figs. 81 to 98. The constant ϕ represents the flow coefficient, i.e., the ratio of velocity through the blade area to blade-tip speed. The constant ψ represents the total static-pressure head as a fraction of fan-blade-tip velocity head. The efficiency, although spoken of as total efficiency, is what we would usually speak of as static efficiency. It is that which corresponds to ψ, being based on the actual over-all static pressure produced, including both turning vanes and diffusers. With these constants in mind these sets of curves can readily be used in design.

One point which deserves mention is the use of Δp_{tot} and Δp_{st}. The first of these is total pressure increase as defined in the list of symbols and from which the efficiency curves on pages 97 to 105 are derived. The second of these Δp_{st} as used in this volume refers sometimes to total theoretical stage head (see Equations 14, 20, and 22, for example), again it is sometimes an actual static-pressure drop which is represented (see Equation 12, also page 79). The definition in the list of symbols regards this quantity purely as the static drop across the fan blade which is not in general its most important usage in this volume.

There are a few typographical errors which might be mentioned:

On page 4, tenth line from the bottom, w_{u_2} should read c_{u_2}.

On page 5, third line from the bottom, dA should read dL.

In Fig. 19, 0.05 should be 0.5; furthermore, the curves of Figs. 18 and 19 should evidently be interchanged.

On page 47, "these" should read "there."

In Table 11, in the third row from the bottom, g_1 should read q_1.

Any serious student of the theory and application of axial-flow fans will find a careful reading of this book of great value.

Problems of the Magnetizing Curve

PROBLEME DER TECHNISCHEN MAGNETISIERUNGSKURVE. By R. Becker, Göttingen. Julius Springer, Berlin, 1938. Paper, 6 × 9 in., v and 172 pp., 102 figs., 16.50 rm.

REVIEWED BY F. BITTER[16]

THE DEVELOPMENT of the theory of ferromagnetism during the last ten years has not only explained many of the peculiarities of actual materials, but has stimulated research workers to examine still unexplained phenomena in greater detail, and to develop magnetic measurements as a tool for studying other metallurgical problems. In this field the German school has led the world, as is nicely demonstrated in this booklet, containing ten papers on vital new developments of interest to all serious students of metals. R. Becker, who organized the meeting at which these papers were first presented, and who did much to stimulate interest in the subject by his own original contributions, contributes the first paper, introductory in nature, describing in a general way today's generally accepted model of a ferromagnetic substance. There follow two papers by K. Sixtus and W. Döring on large Barkhausen discontinuities, which discuss the manner in which regions of reversed magnetization can form and propagate themselves along a wire.

M. Kersten, who collaborated with Becker in his earlier work and who has done much original work on the subject of the properties of mechanically deformed crystals, contributes an article on the interpretation of coercive force. J. L. Snoek continues with a discussion of the coercive force in Fe-Co-Mo and Fe-Ni-Al alloys, discussing in a most convincing way the importance of "inner demagnetization factors" due to the precipitation of nonmagnetic material in a ferromagnetic alloy. Then there are two papers on magnetic aftereffects and their importance in connection with a-c losses by G. Richter and H. Schulze. Some most striking effects in recrystallized carbonyl iron are described and correlated with primary creep. The book ends with two papers on precipitation hardening by G. Masing and W. Gerlach, and one on rates of transformation in steel by H. Lange, emphasizing the usefulness of magnetic methods of observation. These papers have none of that amateurish superficiality that characterizes many of the older papers in which magnetic methods are used in metallurgical investigations.

Work of this caliber, and perhaps even more thorough and elaborate investigations, are needed if magnetic researches are to contribute in an important way to our understanding of the nature of metals and alloys.

Railway News

TRACTION NOUVELLE, January-February, 1936, first year, No. 1 and January-February, 1937, second year, No. 7. Published bimonthly by J. B. Bailliere & Fils, Paris. Price: 1 yr, France, 40 fr; Belgium, 50 fr; other countries, 60 fr.

REVIEWED BY A. I. LIPETZ[17]

AS IS known, the French railways have now in service a great number of Diesel-electric rail cars and trains; they had over 600 by the middle of the summer of 1937. A rail car committee of representatives of all French railways has started a new publication called *Traction Nouvelle*, published by J. B. Bailliere & Fils, 19, Rue Hautefeuille, Paris 6e, as a beautiful bimonthly magazine in an aluminum-finished paper cover. It started in January, 1936, and the first number contained an interesting article on characteristics of rail cars. "Les Coefficients Caracteristiques des Automotrices." In addition to the usual coefficient of resistances of rail cars on track, air resistance, efficiency of transmission to the wheels from the internal-combustion engine, a new coefficient called "nervousness," is introduced, which represents the following:

The accelerations and speeds of the car, or train, are graphically determined in accordance with the power and resistance curves, depending upon the profile of the line, by one of the usual methods of integration of the equation of motion. The results are plotted as velocities in function of time and distance and compared with actual velocity curves obtained after the car has been built and tested. It is usually observed that the ordinates, which represent actual velocities, have a certain relation to the theoretical ordinates, always in the same ratio, less than 1, for the same car. This is explained by the lag in action of the power of the car from the engine to the wheels. This ratio is called the coefficient of nervosity, or nervousness. It has been included in the list of car characteristics adopted by the Permanent Commission of the International Railway Congress Association.

In the January-February issue of 1937 (No. 7 of the *Traction Nouvelle*) appeared an interesting article on a Czechoslovakian rail car by Mr. Jan Leiner. This car is called the "Slovakian Arrow," and has two 165-hp gasoline engines with two electromechanical direct transmissions to the wheels, one engine and one transmission on each truck. The transmission, known under the name "Sousedik," is of the differential electric type, similar to the Entz or Thomas transmissions described in *Mechanical Engineering* for September, 1926, class B-1. This represents a revival of an old idea which is technically sound, and in small units may be even practical. So far on the Czechoslovakian

[17] Chief Consulting Engineer, American Locomotive Company, Schenectady, New York; Nonresident Professor of Locomotive Engineering, Purdue University, West Lafayette, Ind. Mem. A.S.M.E.

car it has given good results. The car and transmission are fully described also in the Bulletin of the International Railway Congress Association (English edition, August, 1937, page 1787).

Buckling

KNICKUNG, KIPPUNG, BEULUNG. By Friedrich Hartmann, Professor an der Technischen Hochschule, Wien. Franz Deuticke, Leipzig and Wien, 1937. 7 × 10 in., vi and 201 pp., 143 figs., 18.40 rm.

REVIEWED BY A. NÁDAI[18]

THIS IS an enlarged introduction to the lectures on statics of wooden and steel constructions given by the author at the Technical University of Wien. It is a monograph devoted exclusively to the subject of the elastic stability of engineering constructions. The number of papers devoted to this part of the theory of elasticity has increased quite considerably during the last ten to twenty years. While in former times it seemed sufficient to treat the cases of the elastic buckling of straight bars and perhaps the conditions of instability of a few frameworks, according to the opinion of the author of the book a summary of the methods for solving stability problems and of the results of investigations of this kind is needed.

The book is written for use at university lectures and as a textbook for advanced students and engineers. It presents this difficult subject in a brief way. Of the eight chapters the following titles may be of interest: The buckling of straight bars with uniform and with variable cross sections, both in the elastic and the plastic range of strains, eccentric compression, buckling of frames and of bars with elastic connections, "Kippung" (lateral buckling of flat bars), buckling of flat plates.

Considerable effort is made in this book to develop the general equations and conditions of buckling. The theory of the inelastic buckling of a straight bar is treated in greater detail following the pioneer work by Engesser and von Kármán. In this chapter the author has added much original work of his own. He has for example, carefully discussed the relation between the shape of a given stress-strain curve for a structural steel and the corresponding shape of the curve for the critical load as a function of the slenderness ratio. While some recent work on this subject of American authors has not been discussed here (Westergaard, Young, and others), other new work, for example by Chwalla on buckling under eccentric loading is reported. An instructive long chapter is devoted to the general theory of the buckling of flat plates loaded in their plane, preceded by a careful derivation of the integral condition known as the "energy method."

Although this monograph contains many subjects which have been treated recently in Timoshenko's "Theory of Elastic Stability" (McGraw-Hill Book Co,. Inc., N. Y., 1936), the book having been carefully and critically written will be welcomed by readers who wish perhaps to study some of these difficult investigations in more detail, which in their originals cannot easily be reached. The book can well be recommended as an up-to-date record of methods dealing with all kinds of stability questions.

DIE KNICKFESTIGKEIT VON STÄBEN UND STABWERKEN. By Julius Ratzersdorfer. Julius Springer, Wien, 1936. Paper, 6 × 9¼ in., ix and 321 pp., 151 figs., 27 rm.

REVIEWED BY N. M. NEWMARK[19]

AS THE title indicates, this book is concerned only with the buckling of bars and of frameworks of bars. With the exception of his comprehensive chapter on the stability of plane and space trusses and frames, the author discusses many of the problems contained in chapters 1 to 4, pages 1 to 238, of Timoshenko's "Theory of Elastic Stability." The manner of treatment, the arrangement, and the point of view offer interesting comparisons to Timoshenko's work.

The book opens with a detailed discussion of the buckling of straight bars of uniform cross section under axial load. The author studies the effect of the various approximations that are customarily made in deriving the critical buckling load. For example, he derives the relation between deflection and load for a bar fixed at one end and loaded axially at the free end, assuming first that the deflections are small, and then removing this restriction. The approach here, as elsewhere in the book, is first by means of the customary approximations, followed by more exact approximations and in some cases by "exact" solutions (within the limitations of the classical "Theory of Elasticity"). The influence of the change in length of the bar is also discussed. These studies are made in order to lead to more precise concepts of the nature of buckling, and also to furnish quantitative estimates of the accuracy of the ordinary procedures.

Other end conditions and types of loading, the influence of the shearing stresses on the stability, and the behavior of bars of constant cross section made of material that does not follow Hooke's law are considered, and comparisons are made between the results of theory and experiment.

In the second chapter the author takes up a study of the deformation of bars subjected to both bending and direct stress. With a consideration of the effect of large deflections it is shown that the deflection does not actually become infinite when the critical load is reached. A treatment is given also of stresses beyond the elastic limit for combined flexure and axial load.

In the third chapter are considered problems of bars of varying cross section with concentrated end thrusts or with varying direct stress along the length of the axis. The cases treated are those in which the moment of inertia or the distributed axial load or both vary according to some power of the distance along the axis.

A brief discussion is given of approximate methods and methods of successive approximations. An illustration is made of Timoshenko's application of Ritz's method as an example of the use of the "energy method" in studying buckling. Several examples are given of the graphical procedure of successive approximations associated with the name of Vianello. It would have been desirable to extend this part of the work so as to present a single procedure capable of general application to problems of buckling of bars of variable cross section both in and beyond the elastic range.

The fourth chapter is concerned with bars having continuous elastic supports, generally with resistance proportional to displacement. Several end conditions are considered, and the case of a bar elastically supported over part of its length is treated.

In the fifth chapter is discussed the buckling of plane and space trusses and of plane frames. The author also treats "framed bars" or built-up columns and compares the theoretical results with test results. It would seem that for practical applications the effects of departure from Hooke's law should be taken into account in the buckling of frames. Also, in any discussion of built-up columns the problem of local buckling or wrinkling is of extreme importance, and such problems are not considered in the present work.

The sixth chapter covers the buckling of bars continuous over fixed or over elastic supports, but not carrying lateral loads. Consideration is given to the problem of lateral stiffening particularly in through bridge trusses without lateral bracing of the upper chord (the pony truss). The seventh chapter concerns the buckling of circular and parabolic arches in their own planes.

[18] Consulting Mechanical Engineer, Westinghouse Research Laboratories, East Pittsburgh, Pa. Mem. A.S.M.E.

[19] Research Assistant Professor of Civil Engineering, University of Illinois, Urbana, Ill.

Professor Ratzersdorfer has contributed a comprehensive and interesting work. The book contains the solution of a number of special problems of practical interest. However, one is led to wonder if the problem of buckling of bars is really as complicated as the length of this treatise (which is by no means an exception in this field) would indicate. There seems to be a necessity for some general approach that does not develop into an entirely new procedure for each special case that arises.

Springs

DIE FEDERN—IHRE GESTALTUNG UND BERECHNUNG. By Dipl.-Ing. Siegfried Gross and Dr.-Ing. Ernest Lehr. V.D.I. Verlag G.M.B.H., Berlin, 1938. Cardboard, 8 × 11½ in., 136 pp., 215 figs., 52 tables. 25 rm.

REVIEWED BY A. M. WAHL[20]

THIS BOOK, published under the auspices of the Springs Committee of the V.D.I., is primarily an attempt to bring together into convenient form for the spring designer the results of a great many research investigations carried out in the last few years, on the calculations of stresses and deflections in mechanical springs of various types. The introduction consists mainly of a brief discussion of the fundamentals of spring design and the properties of spring materials, together with illustrations of numerous practical applications, particularly in the railway and automotive fields. For convenience, the subject matter is divided into: Part 1, springs subjected principally to bending stress (leaf springs, spiral springs, etc.), part 2, springs subjected primarily to torsion stress (helical compression springs), and part 3, springs subjected to direct stress (ring springs).

Because of the importance of leaf springs in railway and automotive work, in part 1 the calculation of such springs is discussed in great detail. Among the particular cases treated are (1) leaf springs with large deflections, (2) effect of variable leaf thickness, (3) effect of interleaf friction, (4) oblique load application, and (5) effect on stress produced by varying the initial curvature of the different leaves. The results of numerous tests and comparison with theory are given. In this part the calculation of spiral and torsion springs is treated as well as that of Belleville and plate springs.

The calculation of helical tension and compression springs both by exact and approximate methods forms the principal subject of part 2. The more exact formulas derived by Göhner for calculating such springs are given, while the results obtained by these methods are compared with those obtained by strain measurements on helical springs of rectangular cross section. Besides the calculation of conical helical springs, the determination of buckling loads and the deflection of laterally loaded helical springs are also treated; in addition a section is devoted to the problem of vibration and surging of valve springs. In the concluding part the calculation of ring springs (as used in railway car buffers) is discussed, a comparison of analytical and experimental results also being included. For the convenience of the practicing engineer the formulas for each type of spring are summarized in convenient form in the final pages of each part of the book; in addition numerical examples throughout serve to illustrate the methods of calculation described.

Although in the reviewer's opinion considerably more data on spring materials and working stresses as used in practice could have been included with benefit, the information contained in the book should make it of considerable value as a reference work for those interested in spring design.

Sound

SOUND. By Arthur Taber Jones, Professor of Physics, Smith College. D. Van Nostrand Company, Inc., New York, 1937. Cloth, 5½ × 8¾ in., xii and 450 pp., figs. 141, $3.50.

REVIEWED BY A. L. KIMBALL[21]

THIS BOOK is unique in that it is largely descriptive in character, in contrast to the usual distinctly analytical presentation of the subject. At the same time it is thoroughly scientific in that no phenomena are taken for granted but are viewed from every angle before conclusions are drawn. The book is delightfully written, in fact the author shows a capacity for clearly explaining physical phenomena so that they are apprehended by the reader with minimum effort.

The author's analysis does not go much further than to cover the case of the standard formula for frequency and the physical explanation of how this formula is applied, including also an interesting derivation from it of the frequency formula for a stretched string based on considerations of similarity. The more mathematical aspects of the subjects of elasticity and elastic vibrations are very little touched upon which most books on sound cover in some detail.

The author shows a broad interest in the general field of the physical phenomena of sound. For example, such matters as what causes the zones of audibility and inaudibility of sound from heavy guns, the question of under what conditions sand on a vibrating plate will become distributed on the antinodes rather than the nodes, the explanation of the ripples in a Kundt tube, the "wolf" note of a violin or cello, are interestingly discussed with details of the experiments which have been made to better understand these phenomena and the conclusions they show.

Among other things the author points out the little known fact that if the energy necessary to raise a blade of grass above the earth as it grows in the spring were all translated into sound, a continuous sound would result which would be clearly audible in a quiet room.

The explanation of the detailed features of thunder as produced by a lightning stroke is the best that the writer of this review has ever seen. The author clearly perceives that echo plays a minor part in the rolling character of thunder, but that its major cause is the extension of the source of this sound through space.

There is considerable material under vibration as applied to different kinds of musical instruments, including bells, which subject has been a specialty of the author in which he has done some fundamental work.

The history of our knowledge of sound phenomena has an appeal to the author in showing the progress of our understanding of them. The reference list is extensive, covering nearly four hundred separate items in the form of footnotes.

Although there is a chapter on technological applications, the subjects of noise prevention and the reproduction of sound by electrical means are not much developed.

There is a rather complete list of questions for possible use in classroom work which are intended as a test of the students' understanding of the subject as well as knowledge of facts presented. The reviewer notes 341 such questions in the text.

There are several short supplementary appendixes covering about ten pages in all at the end of the volume.

Although the book contains over 400 pages it can be covered in three or four evenings by an intelligent and interested reader, though he may not be versed in analytical methods. In fact one of the chief values of the book, aside from its use as a text, is this feature.

[21] General Electric Company, Schenectady, New York. Fellow A.S.M.E.

Bearing Pressures and Cracks

Bearing Pressures Through a Slightly Waved Surface or Through a Nearly Flat Part of a Cylinder, and Related Problems of Cracks

By H. M. WESTERGAARD,[1] CAMBRIDGE, MASS.

The task is undertaken of determining the bearing pressures, and the stresses and deformations created by them, in some cases that differ from those considered by Hertz[2] in his classical study of contact. Thus two solids are examined which, before loading, are in contact along a row of evenly spaced lines in a horizontal plane, as indicated in Fig. 1(*a*). Between these lines the surfaces have a separation defined by a nearly flat cosine wave. A uniform pressure on top of the upper solid creates contact over an area consisting of a row of strips, reduces the separation of the solids between the strips, as suggested in Fig. 1(*b*), and creates contact pressures distributed as indicated in Fig. 1(*c*), with vertical rises in the diagram of pressure at the edges of the strips. At a greater load the width of the strip becomes equal to the wave length, and the contact is complete. At still greater loads the stresses increase as if the two solids were one. The procedure by which this problem is solved is demonstrated first by showing its easy application to some well-known cases, especially Hertz's problem of circular cylinders in contact.[2]

Further applications are to a noncircular cylinder resting on a solid with a flat top, with an initial separation of the surfaces varying as the fourth power of the distance from the initial line of contact; to partial contact of two surfaces which are initially plane, except that one of them has a ridge or several parallel ridges; and to some related problems in which two parts of the same body are partially separated by the forming of one or more cracks.

Notation

x, y	= rectangular coordinates, y vertical
r, θ	= corresponding polar coordinates
z	= $x + iy = re^{i\theta}$ = complex variable
Z	= function of z, Equation [1], defining the stresses by Equations [4] to [6]
$Z', \overline{Z}, \overline{\overline{Z}}$	= derivative and first and second integral of Z, Equations [2]
$\sigma_x, \sigma_y, \tau_{xy}$	= normal stresses and shearing stress in the directions of x and y
ξ, η	= displacements in the directions of x and y
η_0	= displacement η at $y = 0$
s	= initial separation of two surfaces
E, G, μ	= Young's modulus, modulus of elasticity in shear, and Poisson's ratio
F	= Airy's stress function
P	= force on slice parallel to the x,y-plane one unit thick, measurable in pounds per inch
p	= average pressure or tension, measurable in pounds per square inch
a, l	= horizontal distances on axis of x
c, c_1	= constants

Function of a Complex Variable Used as Stress Function

A stress function will be applied of a type which was introduced by Carothers[3] in 1920 and, evidently independently, by Nádai[4] in 1921. Both expressed the significant values in terms of harmonic functions, and both made use of the following fact: A harmonic function of x and y can be obtained as the real part ReZ or the imaginary part ImZ of an analytic function Z of the complex variable $z = x + iy$, with Z being written in the forms

$$Z = Z(z) = Z(x + iy) = \mathrm{Re}Z + i\mathrm{Im}Z \quad \ldots\ldots [1]$$

In the present applications it is expedient, as done by MacGregor,[5] to use the function Z itself as stress function.

The further functions Z', $\overline{Z}$, and $\overline{\overline{Z}}$ are the derivative and first and second integrals of Z, so that

$$Z' = \frac{dZ}{dz}, \quad Z = \frac{d\overline{Z}}{dz}, \quad \overline{Z} = \frac{d\overline{\overline{Z}}}{dz} \quad \ldots\ldots [2]$$

The properties of derivatives are noted

$$\frac{\partial \mathrm{Re}Z}{\partial x} = \frac{\partial \mathrm{Im}Z}{\partial y} = \mathrm{Re}Z', \quad \frac{\partial \mathrm{Im}Z}{\partial x} = -\frac{\partial \mathrm{Re}Z}{\partial y} = \mathrm{Im}Z' \ldots [3]$$

In a restricted but important group of cases the normal stresses and the shearing stress in the directions of x and y can be stated in the form

$$\sigma_x = \mathrm{Re}Z - y\mathrm{Im}Z' \quad \ldots\ldots [4]$$

$$\sigma_y = \mathrm{Re}Z + y\mathrm{Im}Z' \quad \ldots\ldots [5]$$

$$\tau_{xy} = -y\mathrm{Re}Z' \quad \ldots\ldots [6]$$

---

[4] "Über die Spannungsverteilung in einer durch eine Einzelkraft belasteten rechteckigen Platte," by A. Nádai, *Der Bauingenieur*, vol. 2, 1921, pp. 11–16, especially p. 12. Nádai applied the function to express curvatures and twists of elastic slabs. The curvatures and twists can be interpreted as stresses through Airy's stress function.

[5] "The Potential Function Method for the Solution of Two-Dimensional Stress Problems," by C. W. MacGregor, Trans. American Mathematical Society, vol. 38, no. 1, July, 1935, pp. 177–186.

By referring to Equations [3] it is observed that these stresses satisfy the two conditions of equilibrium of the form

$$\frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{xy}}{\partial y} = 0 \quad \ldots\ldots [7]$$

The limitation of this type of solution appears in Equations [4] to [6], which require that

$$\sigma_x = \sigma_y \text{ and } \tau_{xy} = 0 \text{ at } y = 0 \quad \ldots\ldots [8]$$

With deformation in the direction perpendicular to the x, y-plane prevented, the displacements ξ and η in the directions of x and y are defined by the formulas

$$2G\xi = (1 - 2\mu)\,\mathrm{Re}\overline{Z} - y\mathrm{Im}Z \quad \ldots\ldots [9]$$

$$2G\eta = 2(1 - \mu)\,\mathrm{Im}\overline{Z} - y\mathrm{Re}Z \quad \ldots\ldots [10]$$

For, it is found that these displacements define the stresses in Equations [4] to [6] through Hooke's law, which can be stated in the form

$$\sigma_x = 2G\left[\frac{\partial \xi}{\partial x} + \frac{\mu}{1-2\mu}\left(\frac{\partial \xi}{\partial x} + \frac{\partial \eta}{\partial y}\right)\right] \text{ and } \tau_{xy} = G\left(\frac{\partial \xi}{\partial y} + \frac{\partial \eta}{\partial x}\right) \quad \ldots\ldots [11]$$

A useful observation from Equation [10] is that the value of η at $y = 0$ is

$$\eta_0 = \frac{1-\mu}{G}\,\mathrm{Im}\overline{Z} = \frac{2(1-\mu^2)}{E}\,\mathrm{Im}\overline{Z} \quad \ldots\ldots [12]$$

It is noted, furthermore, that the Airy function defining the stresses by the equations

$$\sigma_x = \frac{\partial^2 F}{\partial y^2}, \quad \sigma_y = \frac{\partial^2 F}{\partial x^2}, \quad \text{and} \quad \tau_{xy} = -\frac{\partial^2 F}{\partial x \partial y} \quad \ldots\ldots [13]$$

is

$$F = \mathrm{Re}\overline{Z} + y\mathrm{Im}\overline{Z} \quad \ldots\ldots [14]$$

In a slice parallel to the x, y-plane one unit thick the total vertical force transmitted between two points is the increase of the derivative

$$\frac{\partial F}{\partial x} = \mathrm{Re}\overline{Z} + y\mathrm{Im}Z \quad \ldots\ldots [15]$$

between the points. Similarly, the total horizontal force transmitted between two points is the increase of

$$\partial F/\partial y = y\mathrm{Re}Z \quad \ldots\ldots [16]$$

between the points.

Introductory Application to Boussinesq's Problem

The semi-infinite solid $y \geqq 0$, with y positive downward, is under consideration. The function

$$Z = P/(i\pi z) \quad \ldots\ldots [17]$$

gives

$$\overline{Z} = \frac{P}{i\pi}\log(z/c_1) = \frac{P}{i\pi}\left[\log(r/c) + i\left(\theta - \frac{\pi}{2}\right)\right] \quad \ldots [18]$$

that is

$$\mathrm{Re}\overline{Z} = P[\theta - (\pi/2)]/\pi \quad \ldots\ldots [19]$$

According to Equations [15] and [19], in a slice parallel to the xy-plane and one unit thick the total vertical force transmitted between $\theta = \pi$ and $\theta = 0$ is $-P$. It is concluded that Equation [17] represents the solution of Boussinesq's problem in two dimensions for a normal pressure P concentrated at $z = 0$. The familiar formulas for stresses and displacements are obtained readily by substituting from Equations [17] and [18] in Equations [4], [5], [6], [9], and [10].

Rows of Forces

Equation [17] suggests consideration of two modified functions

$$Z_1 = -i\frac{P}{l}\cot(\pi z/l) \text{ and } Z_2 = -i\frac{P}{l\sin(\pi z/l)} \quad \ldots [20]$$

Near $z = 0$ both approach Z in Equation [17]. Further inspection shows that Z_1 represents a row of equal pressures P at $z = 0, \pm l, \pm 2l, \ldots$, and Z_2 represents a row of pressures P at $z = 0, \pm 2l, \pm 4l, \ldots$ and a row of pulls P at $z = \pm l, \pm 3l, \pm 5l, \ldots$ on the solid $y \geqq 0$. When y becomes great, Z_1 converges toward $-P/l$, making the stresses in Equations [4] to [6] converge toward a uniform pressure P/l; while Z_2 converges toward zero, making the stresses converge toward zero, as they should under the self-balancing load.

Demonstration by Application to Hertz's Problem of Two Circular Cylinders in Contact

The solid $y \geqq 0$ is considered again. As stress function is chosen

$$Z = -\frac{2P}{\pi a^2}\left[\sqrt{(a^2 - z^2)} + iz\right] \quad \ldots\ldots [21]$$

$$\text{or} \quad Z = -\frac{2P}{\pi a^2}\left[\sqrt{(a^2 - x^2 + y^2 - i\,2xy)} + ix - y\right] \quad \ldots [22]$$

At $y = 0$ the shearing stress $\tau_{xy} = 0$, and the normal stresses, according to Equations [4] and [5], are both equal to $\mathrm{Re}Z$. Accordingly

$$\sigma_x = \sigma_y = 0 \text{ at } y = 0,\ x < -a \text{ or } x > a \quad \ldots\ldots [23]$$

$$\sigma_x = \sigma_y = -(2P/\pi a^2)\sqrt{(a^2 - x^2)} \quad \text{at } y = 0, \quad -a < x < a \quad \ldots\ldots [24]$$

Equations [23] and [24] show that the diagram of pressures on the surface $y = 0$ can be drawn as a half-ellipse between $x = -a$ and $x = a$; outside there is no load. The total pressure on the slice one unit thick is P.

When z becomes numerically great, with y remaining positive, one may write

$$\sqrt{(a^2 - z^2)} = -iz\sqrt{[1 - (a^2/z^2)]} = -iz\,(1 - a^2/2z^2 - \ldots) \quad \ldots [25]$$

Therefore, Z in Equation [21] converges toward Z in Equation [17], which represents Boussinesq's problem.

In the interval $-a < x < a$ at $y = 0$ Equations [12] and [22] give

$$\frac{d\eta_0}{dx} = \frac{2(1-\mu^2)}{E}\,\mathrm{Im}Z = -\frac{4(1-\mu^2)Px}{\pi E a^2} \quad \ldots\ldots [26]$$

that is, along the axis of x there is produced a constant concave curvature

$$\frac{1}{R} = -\frac{d^2\eta_0}{dx^2} = \frac{4(1-\mu^2)P}{\pi E a^2} \quad \ldots\ldots [27]$$

If instead of being initially flat along the axis of x the surface has an initial convex curvature equal to that in Equation [27], under the pressures defined by Equation [24] the surface will be flattened out and become plane in the interval $-a < x < a$; outside this interval it will be flattened out less.

It follows that if two parallel cylinders with radii R are pressed together by the load P per unit of length, the width $2a$ of the strip of contact will be defined by a in Equation [27], which agrees

with Hertz's classical solution. With a known, the contact pressures are defined by Equation [24] and the stresses and displacements in the surrounding region by Equations [21], [4], [5], [6], [9], and [10].

Bearing Pressure Through Slightly Waved Surface

Equation [21] suggests investigation of the stress function

$$Z = -\frac{2p\cos(\pi z/l)}{\sin^2(\pi a/l)}\left\{\sqrt{[\sin^2(\pi a/l) - \sin^2(\pi z/l)]} + i\sin(\pi z/l)\right\} \quad \ldots [28]$$

as applying to the solid $y \geqq 0$. It is assumed that $a < l/2$. By computing as in Equation [25], it is found that when y is positive and great compared with a, Equation [28] may be replaced by

$$Z = -ip\cot(\pi z/l) \quad \ldots [29]$$

According to the comments on Equations [20], Z in Equation [29] represents a row of pressures pl with spacing l at $y = 0$, and a uniform pressure p at great values of y.

At the surface $y = 0$ one finds in the interval $-a < x < a$

$$\sigma_x = \sigma_y = \mathrm{Re}Z = -\frac{2p\cos(\pi x/l)}{\sin^2(\pi a/l)}\sqrt{[\sin^2(\pi a/l) - \sin^2(\pi x/l)]} \quad \ldots [30]$$

and in the interval $a < x < l - a$

$$\sigma_x = \sigma_y = \mathrm{Re}Z = 0 \quad \ldots [31]$$

The function Z is periodic, and the period is l. The values are repeated in the similar intervals. The strips $nl - a < x < nl + a$ are loaded by pressures $-\sigma_y$ defined numerically by Equation [30]; the remaining strips are unloaded.

Within the loaded strips of the surface Equation [28] gives

$$\mathrm{Im}Z = -\frac{p\sin(2\pi x/l)}{\sin^2(\pi a/l)} \quad \ldots [32]$$

Over the whole surface $\mathrm{Im}Z$ is antisymmetrical with respect to the center lines $x = nl/2$ of the strips. By referring to Equation [12] it is then found that within the loaded strips the deflection of the surface can be stated as

$$\eta_0 = \frac{2(1-\mu^2)}{E}\mathrm{Im}\bar{Z} = \frac{(1-\mu^2)pl}{\pi E}\frac{[\cos(2\pi x/l) - 1]}{\sin^2(\pi a/l)} \quad \ldots [33]$$

with the integration constant being the same for all the loaded strips.

Assume now that instead of being initially flat the surface is slightly waved, having the equation

$$y_0 = \frac{c}{4}[1 - \cos(2\pi x/l)] \quad \ldots [34]$$

with

$$c = \frac{4(1-\mu^2)pl}{\pi E\sin^2(\pi a/l)} \quad \ldots [35]$$

Then under the pressures defined by Equation [30] the ordinates $y_0 + \eta_0$ of the deformed surface will be zero within the loaded strips. The loaded strips will be flattened out and be contained in a single plane. A further examination of $\mathrm{Im}Z$ as defined by Equation [28] shows that $y_0 + \eta_0$ will be positive between the loaded strips.

It is concluded that if another solid of the same material and shape is placed in contact with the one considered, so that the axis of x becomes an axis of symmetry, and if thereafter a uniform pressure p is produced at numerically large values of y, the contact pressures will be as defined by Equation [30]; the

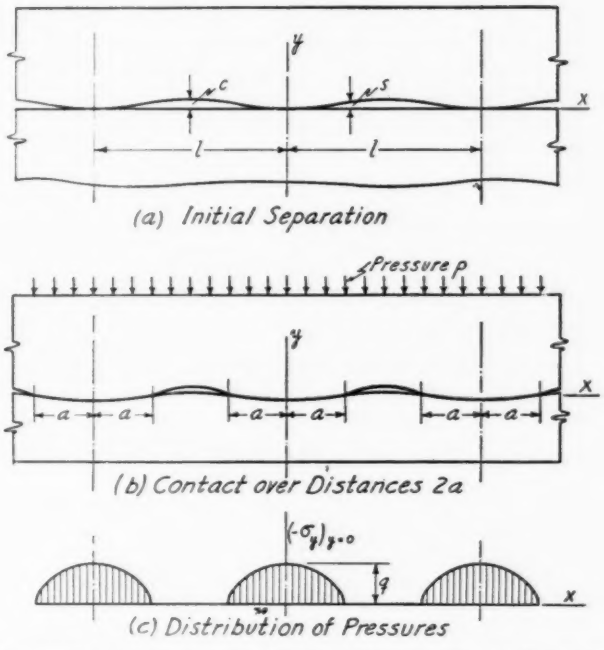

Fig. 1 Bearing Pressures Through Slightly Waved Surface

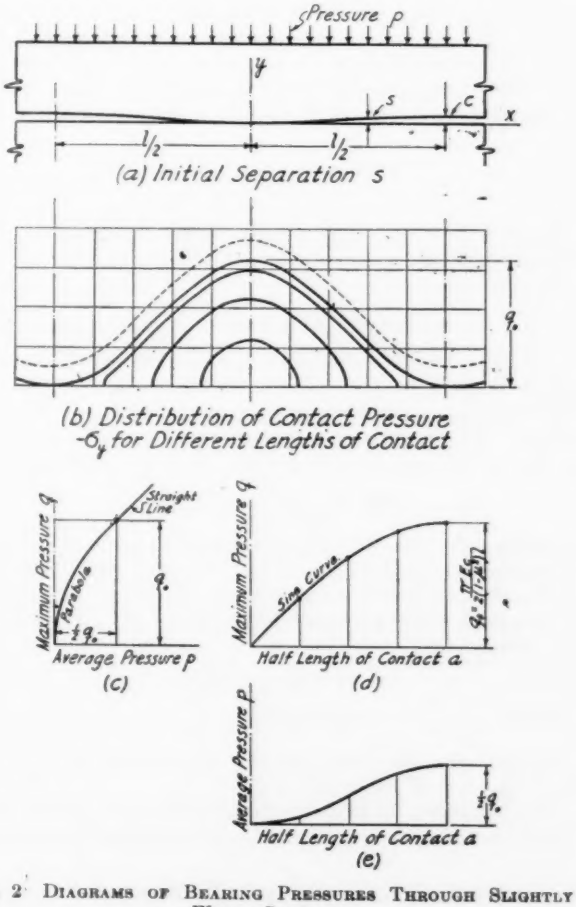

Fig. 2 Diagrams of Bearing Pressures Through Slightly Waved Surface

area of contact through which the pressures are transmitted will consist of the strips of width $2a$ defined by Equation [35]. Equations [34] and [35] are verified by Equation [27] when a is small compared with l.

It is noted that the initial separation of the two surfaces, before pressure is applied, is

$$s = (c/2)[1 - \cos(2\pi x/l)] = c \sin^2(\pi x/l), \quad s_{max} = c \ldots [36]$$

The conclusions that were drawn continue to apply if the two nearly flat surfaces in contact have a different shape, as long as the initial separation is defined by Equations [36].

Fig. 1 illustrates this case. Fig. 2 shows some results obtained from Equations [30] and [35].

Noncircular Cylinder With Nearly Flat Bottom

The function

$$Z = -\frac{8P}{3\pi a^4}\left[(z^2 + a^2/2)\sqrt{(a^2 - z^2)} + iz^3\right] \ldots [37]$$

applied to the solid $y \geqq 0$, is examined first for numerically great values of z. By writing

$$\sqrt{(a^2 - z^2)} = -iz\left(1 - \frac{a^2}{2z^2} - \frac{a^4}{8z^4} - \ldots\right) \ldots [38]$$

Z in Equation [37] is found to converge toward Z in Equation [17], which represents Boussinesq's problem. Again, at distances great compared with a the stresses are as in Boussinesq's problem, and the total load on the slice one unit wide is P.

At $y = 0$ only the interval $-a < x < a$ is loaded; the pressures are $-\mathrm{Re}Z$. At $x = 0$ the pressure is $8/3\pi$ times the average, that is, less than the average; the maximum pressure occurs at some distance from the center of the load. These pressures can be produced by contact of two solids. The required initial separation s is computed by considering the interval $-a < x < a$. One finds

$$s = -\frac{4(1-\mu^2)}{E}\,\mathrm{Im}\bar{Z} = \frac{8(1-\mu^2)P}{3\pi E a^4}\,x^4 \ldots [39]$$

The lower solid may have a flat top while the upper solid is a noncircular cylinder shaped at the bottom according to a parabola of fourth degree.

Flat Surfaces With One or More Ridges

Fig. 3(a) shows two solids with surfaces that are initially plane except for a single ridge on one of the surfaces at $x = 0$. Under the pressure p contact is missing in the intervals $-a < x < 0$ and $0 < x < a$. The same situation may be created by driving a plug in between the two surfaces. The stress function

$$Z = -p\sqrt{(1 - a^2/z^2)} \ldots [40]$$

represents this case, with the provision that a uniform horizontal tension, for example, $\sigma_x = p$ may be superposed. Fig. 3(b) shows the distribution of the pressures of contact. The force P at the ridge is found by stating Z near $z = 0$ for $y > 0$ in the two forms

$$Z = -ipa/z = P/(i\pi z) \ldots [41]$$

which gives

$$P = \pi pa \ldots [42]$$

The value of a will depend not only on p but also on the height and sharpness of the ridge.

Fig. 3(c) shows the related problem of a number of equal parallel ridges with spacing l. The corresponding stress function is

$$Z = -p\sqrt{\left[1 - \frac{\sin^2(\pi a/l)}{\sin^2(\pi z/l)}\right]} \ldots [43]$$

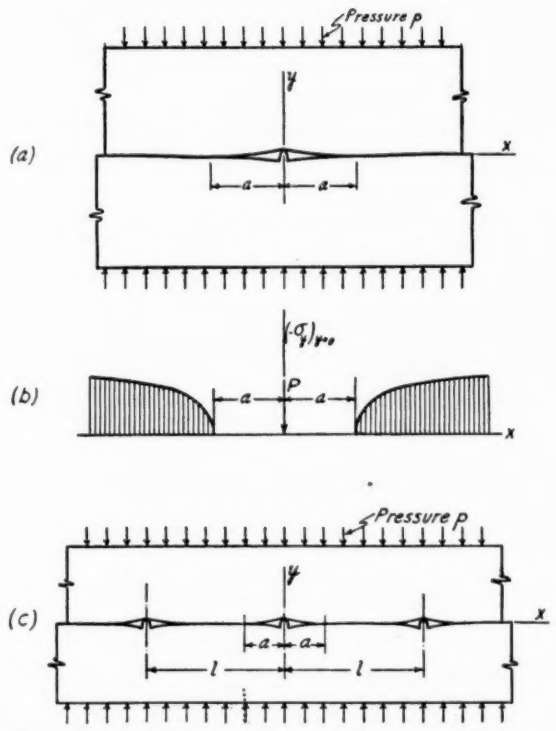

Fig. 3 Contact Between Initially Flat Surfaces With Ridges

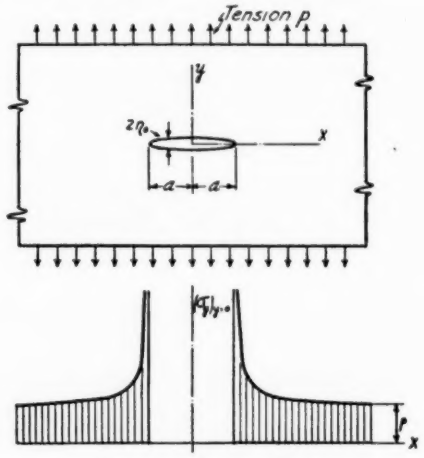

Fig. 4 Internal Crack

Internal Crack

Fig. 4 shows an internal crack which has opened from $z = -a$ to $z = a$ under the influence of an average tension p. The function

$$Z = p/\sqrt{[1 - (a^2/z^2)]} \ldots [44]$$

solves the problem. Z converges toward p when z becomes numerically great. At $y = 0$ one finds outside the crack the tension

$$\sigma_y = p/\sqrt{[1 - (a^2/x^2)]} \ldots [45]$$

and within the length of the crack the opening

$$2\eta_0 = \frac{4(1-\mu^2)}{E}\,\mathrm{Im}\bar{Z} = \frac{4(1-\mu^2)p}{E}\sqrt{(a^2 - x^2)} \ldots [46]$$

which shows the shape of the crack to be elliptic. The concentration of stress and the infinite slope $d\eta_0/dx$ at $x = \pm a$ are subject to the usual interpretation applicable to singularities. A uniform horizontal compressive stress p may be superposed without disturbing the remaining features of the solution.

Equation [44] suggests examination of the function

$$Z = p \Big/ \sqrt{\left[1 - \frac{\sin^2(\pi a/l)}{\sin^2(\pi z/l)}\right]} \quad \ldots\ldots\ldots\ldots [47]$$

At numerically great values of y this function converges toward p and defines a uniform tension p. At $y = 0$ the function accounts for a system of cracks, each of length $2a$, with centers at $x = 0, \pm l, \pm 2l, \ldots$.

The function

$$Z_1 = Z - p \quad \ldots\ldots\ldots\ldots\ldots\ldots [48]$$

with Z as in Equation [44] or [47], accounts for a crack or a system of cracks at $y = 0$, created by a liquid pressure p in the cracks as the only load.

Crack Opened by Wedge

Fig. 5(*a*) shows a crack opened by a wedge exerting pressures P. The stress functions

$$Z_1 = \frac{P}{\pi(a+z)}\sqrt{\frac{a}{z}} \quad \text{and} \quad Z_2 = -\frac{P}{\pi(a+z)}\sqrt{\frac{z}{a}} \quad \ldots [49][50]$$

represent two possible solutions, which require different loads at the outer boundary. Fig. 5(*b*) and (*c*), show the corresponding diagrams of stresses at $y = 0$. A change of the load on the outer boundary may bring about the change from Z_1 to Z_2, replacing the concentration of tension in Fig. 5(*b*) by the diagram of finite compressive stresses in Fig. 5(*c*). The form of the latter diagram near $x = 0$, with the vertical tangent at $x = 0$, should be considered as characteristic of brittle materials, such as concrete.[6]

[6] "Stresses at a Crack, Size of the Crack, and the Bending of Reinforced Concrete," by H. M. Westergaard, *Journal* American Concrete Inst., November-December, 1933, or, Proceedings, vol. 30, 1934, pp. 93–102. Contains an analysis of this feature of cracks.

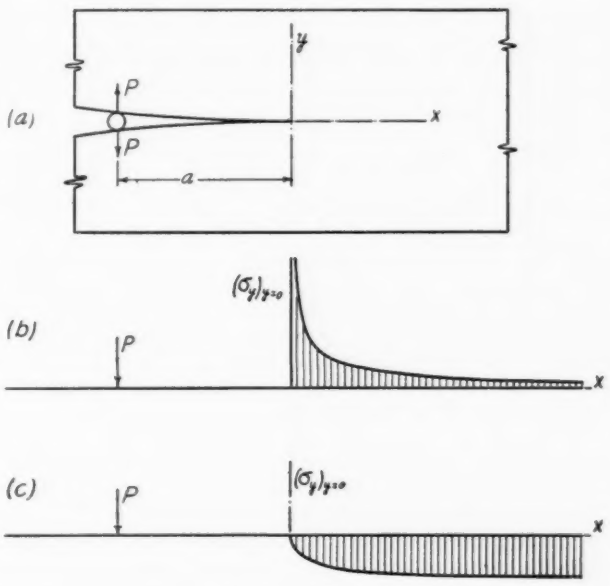

Fig. 5 Crack Opened by Wedge

An internal crack which has been opened between $z = -a$ and $z = a$ by a wedge exerting the pressure P at $z = 0$ is accounted for by the stress function

$$Z = Pa/[\pi z\sqrt{(z^2 - a^2)}] \quad \ldots\ldots\ldots\ldots [51]$$

This function shows concentration of tension at $z = \pm a$, and vanishing stresses at great distances from the crack. If an external pressure is superposed, of the magnitude p defined by Equation [42], Z in Equation [51] will be replaced by Z in Equation [40], and the concentration of tension is replaced by moderate compressive stresses.

Concluding Comment

It is easy to add further examples. Those that have been shown indicate a type of problem to which the method that was used lends itself.

The Forces Required for Rolling Steel Strip Under Tension

By A. NÁDAI,[1] EAST PITTSBURGH, PA.

In the continuous mills which have been installed during the last ten years, wide strips of steel are being rolled hot or cold. While the sheets are reduced under the lateral pressure of the rolls, tensile stresses are set up in the rolled strips. The influence of front or of back tension on the roll pressures is investigated and a theory developed for the rolling process considering tension.

The localized compression of wide sheets or strips under simultaneous application of tensile stresses is discussed under various conditions of surface friction, such as solid friction, uniform surface shearing stresses or a resistance to slipping proportional to the relative velocity of slip. Simultaneous pulling reduces considerably the pressures otherwise required for deforming metal through concentrated compression.

The theory of the rolling of wide sheets is discussed with particular reference to the influence of front and of back tension upon the rolling pressures and the results of such computations are shown in several examples. Treatment of the equations aims at a simplified use of certain variables and parameters which are needed in such computations.

I INTRODUCTION

IN VARIOUS large steel plants of the United States continuous hot- and cold-strip mills have been recently installed on a large scale. With these mills the art of making thin sheets and plates of steel has been changed and improved quite considerably, if not entirely revolutionized. Thin sheets of steel are now being rolled to a width of 70 in. or more in lengths of several hundred feet, with the same strip being engaged in 5 or 6 heavy rollstands. Improved designs of the driving and rolling equipment have made possible the production on a more economical basis of wide strips to supply the large-scale consumption of this kind of product in other industries. The advances in the manufacturing process of forming thin steel plates are: Increase of length and width of sheets, higher velocities of rolling (delivery speeds after the last stand of from 1200 to 1500 fpm or more are commonly used), the simultaneous pulling of sheets between stands, better uniformity and smoothness of surface, and an improved inner structure of the rolled products. The outstanding change perhaps was the application of large tensile stresses to the strips which, during the rolling operation, pull the sheets in the direction of rolling. This in turn brought with it the necessity of developing new means for controlling the tensile forces as well as influencing the rolling pressures required for the plastic forming of the sheets.

The ease of control of the torques and velocities of electric motors and motor generator sets which drive the mills, when compared with the driving machines of large mills used a generation ago, proved here invaluable. The electric drive made these developments possible. For example five or more consecutive pairs of heavy rolls are speeded up or slowed down in as many rollstands during the rolling of a long strip. At the same time ratios of the peripheral velocities of the pairs of working rolls must be maintained to hold constant the prescribed drafts (reductions in thickness of the sheet) to be taken in each of the consecutive stands.

For deforming metal between two rolls a torque is required which consists of two portions—one is the resultant of all the roll pressures p in the contact zone times its lever arm and the second portion is the difference between the resultants of the front and the rear tensions times the roll radius. One of the aims of this paper is to determine the pressure distribution under the rolls and thereby establish the position of the resultant of the roll pressures. Where single stands are used or special operations are to be carried out, present tendencies seem to be to increase back tension rather than front pull. One of the main reasons why utilization of more tension during rolling proved to be advantageous is evidently but another expression of the well-known facts about the plastic yielding of the ductile metals under combined stresses. If an element of a metal is deformed by compression, the stress can be diminished by applying tensile stresses at right angles to the compression direction, for example in a sheet, in the plane of the sheet (small additional tensile or compression stresses which may be present in the third direction which is mutually perpendicular to the principal compression and to the one in which the tensile stress was assumed, are of secondary importance) because yielding is controlled by the major of the principal-stress differences. Simultaneous pulling reduces the heavy rolling pressures otherwise required for deforming the metal and with them also the friction in the contact areas between the rolls and sheet. Thus wear and abrasion of the surface of the rolls are considerably lessened. This is an important factor in the maintenance costs of large mills. At the same time the uniformity of the structure of the metal sheets is improved. Large roll pressures mean massive frames, expensive bearings, power losses, and excessive wear. The power required for the pure plastic forming (compression) of the metal under the rolls increases if the frictional resistance becomes larger during the unavoidable forward and backward slipping of the moving particles of the metal along the contact area between the rolls and the compressed sheet. It is also of importance to note that the flow changes its character with increasing frictional surface resistance. The larger the friction is the more nonuniform the unit shearing strains must become in both surface layers of the sheet. Tension makes the flow more uniform through the entire cross section of a rolled sheet, and the structure is improved.

Recent developments in this field have been quite remarkable and practical questions related to the rolling of strips have been dealt with in several papers published in the last few years which cannot be quoted here in detail, but theoretical investigations on plastic flow which are adaptable to the rolling process and to details to be treated in this paper are comparatively scarce. In this connection reference to a paper prepared by Th. von

[1] Consulting Mechanical Engineer, Westinghouse Research Laboratories. Mem. A.S.M.E.

Presented at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, N. Y., December 5–9, 1938.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until August 10, 1939, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

Kármán[2] and to the extensive pioneer work by E. Siebel[3,6] done at the Steel Institute in Düsseldorf and that by W. Trinks[4] at Carnegie Institute of Technology in Pittsburgh should be made.[5] Some ideas which have been worked out in a revised way in what follows were the subjects of discussions the writer had several years ago with L. Prandtl in Göttingen and with E. Siebel. Concerning questions of rolling with tension the author is indebted for much valuable information to P. G. Lessmann in Pittsburgh with whom these details were frequently discussed recently.

An analysis of the forces required for rolling thin sheets has to consider the plastic compression of the elements of material passing under the rolls while at the same time considerable stresses act in the direction of rolling and probably minor stresses in the direction parallel to the roll axis. The frictional forces in the areas of contact have to be considered. The following factors seem to be of importance: (1) The effect of the speed of plastic deformation upon the yield stresses in the piece to be worked, particularly in hot rolling; (2) strain hardening in cold rolling; (3) the influence of the friction—extreme-pressure lubricants may be applied in the contact surfaces between the rolls and the steel sheet; (4) the elastic deflection of the heavily loaded backing-up rolls in bending; (5) "crowning" of the working rolls; (6) elastic flattening of these latter in the arc of contact; and (7) the elasticity of the rollstand. These questions can be treated only step by step and gradually. When rolling very thin sheets under heavy pressures, the radius of curvature of the rolls is increased in the area of contact so much that the original radius r of the undeformed working rolls is not defining the conditions with regard to reduction and draft. When the elasticity of various parts of the frame of the rollstands and of the rolls must be considered, the roll pressures, the tension in the strips, the curvatures of the cylinders, and the drafts will become functionally dependent on each other, particularly when very thin sheets are to be rolled.

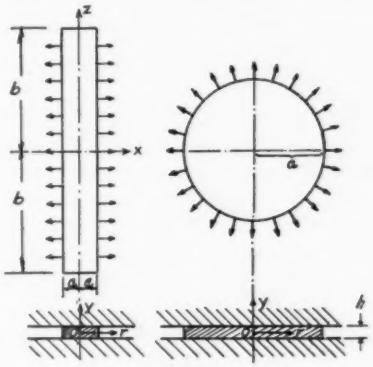
In the present paper the plastic compressing of thin sheets will be considered first and the influence of various types of frictional resistance. The effect of front and back tension on the strips will be discussed but it will be assumed that there is no spreading of sheets in the direction parallel to the axis of the roll. The elastic flattening of the roll cylinders will be dealt with in a later paper.

II COMPRESSION OF A THIN SHEET OF MATERIAL

Some simple cases of compression will be mentioned first, for which it is easy to compute the distribution of the pressures and which may serve as typical examples of what might be expected under more complicated conditions. Friction of course is to be considered acting along the surface of plates and opposing the flow of the compressed solids.

(A) Parallel Flow in Viscous Layer in Compression

A material is supposed to fill the space between two parallel hard plates of rectangular shape. For a steady slow flow of such a solid following the law of a very viscous substance the forces can be assumed to be in equilibrium. It is assumed that the distance h between the plates is small and that the strains are infinitesimal. If the length of one pair of sides $2b$ of the rectangular compression plates is much larger than the length of the other pair $2a$, flow occurs in parallel planes, for which the x, y-plane may be chosen. (Fig. 1.) In other words, spreading of the material in the direction of the z-axis is excluded. The velocity components of flow are u and v parallel to the x- and y-axes, the coefficient of viscosity of the substance is η, and p is



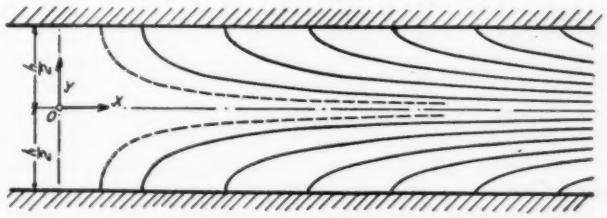


Fig. 1 Parallel Flow

Fig. 2 Radial Flow

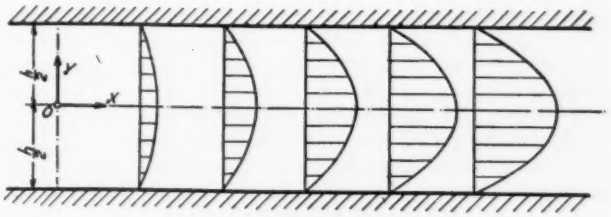

Fig. 3 Streamlines

Fig. 4 Velocities u for Parallel Flow

the pressure perpendicular to the middle plane $y = 0$ of the flat rectangular body. Suppose that the substance adheres to the compression plates. Then the boundary conditions are

$$y = \pm h/2, \quad u = 0, \quad v = \pm v_0 \ldots\ldots\ldots\ldots [1]$$

in which v_0 is the velocity with which each of the plates is moving toward the middle plane. The stream function

$$\psi = v_0 x(3h^2 y - 4y^3)/h^3 \ldots\ldots\ldots\ldots [2]$$

satisfies the imposed conditions and Equations [1] furnishing for the two velocity components of flow

Trinks in *Blast Furnace and Steel Plant*. See "Roll Pressures in Hot Rolling," September, 1937; "The Mechanics of Cold Rolling," March, 1937; "Pressures and Roll Flattening in Cold Rolling," June, 1937.

[5] With reference to the forming of metals compare also: "Grundbegriffe der Mechanischen Technologie der Metalle," by G. Sachs, Akademische verlagsgesellschaft, Leipzig, 1925.

$$u = \frac{\partial \psi}{\partial y} = \frac{3v_0 x}{h}\left(1 - \frac{4y^2}{h^2}\right), \quad v = -\frac{\partial \psi}{\partial x} = -v_0\left(\frac{3y}{h} - \frac{4y^3}{h^3}\right) \quad \ldots\ldots\ldots [3]$$

The streamlines of this flow are shown in Fig. 3, the velocities u in Fig. 4. The pressure p which is expressed by the formula

$$p = 12\eta v_0(a^2 - x^2)/h^3 \ldots\ldots\ldots\ldots\ldots [4]$$

changes according to a parabola with the distance x from the origin. The maximum pressure

$$p_{max} = 12\eta v_0 a^2/h^3 \ldots\ldots\ldots\ldots\ldots [5]$$

is proportional to the square of the width ($2a$) of the compression plates and inversely proportional to the cube of the distance (h) between them. The total load is equal to

$$P = (2/3)(2a)(2b)p_{max} = 32\eta a^3 b v_0/h^3 \ldots\ldots\ldots [6]$$

(B) Radial Flow in Viscous Layer

If the compression plates are circular (Fig. 2) with a radius a the pressure at a distance r from the center (Fig. 5) is equal to

$$p = 6\eta v_0(a^2 - r^2)/h^3 \ldots\ldots\ldots\ldots\ldots [7]$$

The maximum pressure is $p_{max} = 6\eta v_0 a^2/h^3 \ldots\ldots\ldots\ldots\ldots [8]$

The load is $P = \pi a^2 p_{max}/2 = 3\eta\pi v_0 a^4/h^3 \ldots\ldots\ldots\ldots [9]$

It is noted that all stream lines of the flow (Fig. 3) start perpendicularly to the compression plates and that the maximum shearing stresses act along these latter. The shearing stresses τ in the interior of the substance are

$$\tau = -24\eta v_0 xy/h^3 \quad \text{and} \quad \tau = -12\eta v_0 ry/h^3 \ldots\ldots [10]\ [11]$$

respectively. These formulas may be useful for orientation.

(C) Plastic Solid in Compression

Suppose again, as in Fig. 1, that a solid is squeezed between two long parallel rectangular plates $2b \times 2a$ the distance h between which is small. Suppose that $2b$ is much larger than $2a$. Taking again one of the planes in which the material flows as the xy-plane (Fig. 6) the distribution of the pressures $p = f(x)$ can in a first approximation be found. It is assumed that plastic strains remain infinitesimal and that the three components of normal stress σ_x, σ_y, and σ_z can be taken as the principal stresses in every point of the solid. In other words, the influence of the shearing stress τ_{xy} on the condition of plasticity is neglected. The letter τ will be used for this stress later when the condition of equilibrium has to be considered. The influence of these shearing stresses τ in the bounding surfaces of the sheet $y = \pm h/2$ in which it appears as friction will therefore be taken into consideration. Under these assumptions the condition of plastic yielding is expressed by

$$(\sigma_x - \sigma_y)^2 + (\sigma_y - \sigma_z)^2 + (\sigma_z - \sigma_x)^2 = 2\sigma_0^2 \ldots\ldots [12]$$

in which σ_0 is the yield stress in pure tension. Because the distance h between the compression plates is small

$$\sigma_y = -p \ldots\ldots\ldots\ldots\ldots [13]$$

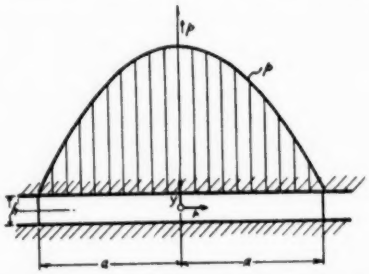
throughout the solid, where p is the pressure exerted by the compression plates at a distance x from the origin, Fig. 6. The strain ϵ_z is equal to zero, that is, it is assumed that there is no "spreading" in the z-direction. Therefore

$$\sigma_z = (\sigma_x + \sigma_y)/2 = (\sigma_x - p)/2 \ldots\ldots\ldots [14]$$

The stress σ_z is determined after substituting Equations [13] and [14] in the equation of yielding [12], which gives $\sigma_x + p = \pm 2\sigma_0/\sqrt{3}$ and, taking the positive sign

$$\sigma_x + p = 2\sigma_0/\sqrt{3} = \text{const} \ldots\ldots\ldots\ldots [15]$$

This constant $2\sigma_0/\sqrt{3} = 1.155\sigma_0$ will be called the "constrained yield strength" for tension and will be designated as s_0. It is the tensile yield stress in a bar, which is allowed to contract freely in one of the lateral directions, while it is constrained not to deform in the other lateral direction (this latter is the direction,



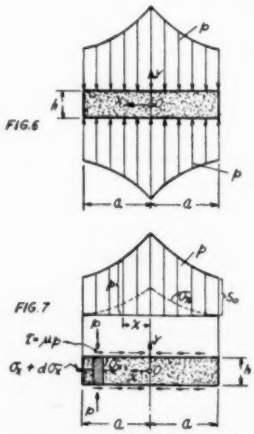


Fig. 5 Distribution of Pressure p in Radial Flow

Figs. 6 and 7 Plastic Solid in Compression

in which spreading in the sheet was excluded). It is seen from Equation [15] that for plastic yielding (in first approximation) in a wide sheet the sum of the normal stress σ_x and of the pressure p remains constant and equal to the constrained yield strength s_0:

$$\sigma_x + p = s_0 \ldots\ldots\ldots\ldots\ldots [16]$$

To this must now be added the condition for equilibrium of the horizontal forces deforming any small column of material of the substance under compression (Fig. 7), taking into consideration the frictional resistance or a shearing stress τ along the compression plates. This condition is

$$d\sigma_x/dx = -dp/dx = 2\tau/h \ldots\ldots\ldots\ldots [17]$$

Several kinds of frictional resistance may be considered:

(1) *Assume Dry Friction Between the Plastic Solid and the Plate.* Then the shearing stress $\tau = \mu p$ where μ is the coefficient of friction. Using Equation [17]

$$dp/dx = -2\mu p/h \ldots\ldots\ldots\ldots\ldots [18]$$

is obtained. When the edge $x = a$ is free of stress, $\sigma_x = 0$ for $x = a$ and therefore $p = s_0$ and the pressure p becomes when $o < x < a$

$$p = s_0 e^{2\mu(a-x)/h} \ldots\ldots\ldots\ldots\ldots [19]$$

If $-a < x < 0$ the negative sign before x in the exponent has to be changed to a plus sign. These two pressure curves are plotted in Fig. 7. When on the other hand the compressed sheet is simultaneously subjected to tensile forces at right angles to the direction of the compression it is easy to see that the pressures p must follow the same exponential law but that they are reduced. It is assumed that the compression plates remain parallel as they are approaching each other. If the compressed sheet is subjected to a tension equal to $\sigma_x = \sigma_1$ on the left side

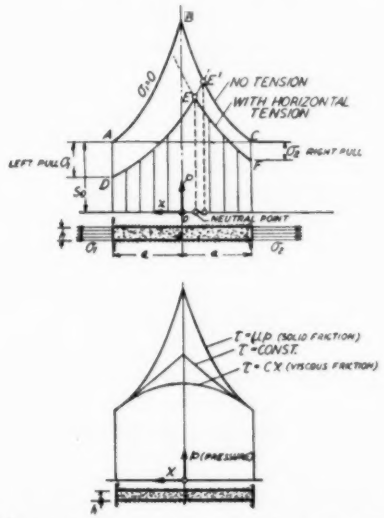

FIG. 8 PRESSURE CURVES FOR PLASTIC SOLID

FIG. 9 PRESSURE CURVES $p = f(x)$ FOR PLASTIC SOLID

of the compressed portion ($x = +a$) and a tension of $\sigma_x = \sigma_2$ on the right side (for $x = -a$) of it, two new pressure curves are obtained

$$\left.\begin{aligned} &\text{left curve,} \quad p = (s_0 - \sigma_1)e^{2\mu(a-x)/h} \\ &\text{right curve,} \quad p = (s_0 - \sigma_2)e^{2\mu(a+x)/h} \end{aligned}\right\} \quad \ldots\ldots\ldots [20]$$

as indicated in Fig. 8. Only the portions DE and EF of these are to be taken. Their point of intersection E defines a point in the compression plane, at which the frictional forces τ must change the direction in which they act. This point has been called the "neutral point" by Trinks in applications to rolling pressures. Its position depends on the tensions σ_x and one can see that it shifts away from the side on which more pull is applied.

Conditions with regard to the friction in the case of rolling may be very different under different conditions. Unfortunately not much is known about these conditions or even about the type of frictional forces which are active in the contact areas of heavily loaded working rolls. During hot rolling of billets when a scale covers these latter and hot water or steam may or may not be present in the contact areas, conditions may be very different from those during cold rolling, after the sheets have been cleaned by pickling in acid solutions. And again while large reductions in pickled strips are being taken cold and frequently in the presence of a lubricant which has been applied on the surface of the sheet, the friction may be very different from that which is active during a skin pass, where the reduction is quite small and no lubricant is used. It seems probable however, that neither a clear case of "solid" friction nor of an "oil film" showing simple fluid or viscous resistance can be present or representative of the conditions during cold rolling. The extremely high local pressures in the contact areas (of the order of 100,000 lb per sq in.) exclude the formation of the latter with certainty. However the assumption of dry friction, according to which $\tau = \mu p$ and the coefficient of friction μ should be independent of the pressure and of the relative velocity of slip between sheet and roll (an assumption which has been used exclusively in the theoretical work on the rolling process), seems also open to criticism. It leads to various conclusions which are not so well supported by tests.

The curves in Fig. 8 bring out a consequence of the assumption. The pressure curves $p = f(x)$ show a sharp peak, which is the more pronounced, the larger μ is assumed. The actual measurements of the pressures in the contact area of rolls by E. Siebel and W. Lueg[6] do not show such sharp breaks but more or less rounded maxima. (The finite dimensions of the piezoelectric pressure gages used by them would account only partially for this rounding off of the pressure curves near their maxima.)

Another consequence of the assumption $\tau = \mu p$ should also be mentioned. If $\tau = \mu p$ the stress τ must increase with the pressure p. A limit to this is however set by every material itself. If the pressure is sufficiently high due to the increase of the tangential resistance either the tensile strength or the plastic limit of the material must finally be reached. Let σ_0 be the yield stress in pure tension. The maximum shearing stress to which a plastic material can be subjected is $\tau_m = \sigma_0/\sqrt{3}$. The friction cannot become larger than τ_m. Hence a maximum pressure p_m must exist, at which the shearing stresses produced by dry friction just becomes equal to τ_m. This pressure is equal to

$$p_m = \sigma_0/(\mu\sqrt{3}) = s_0/2\mu \ldots\ldots\ldots\ldots [21]$$

It should be noted that in the preceding and following considerations the effect of strain hardening is not considered. When for example $\mu = 1/4$, this pressure would be equal to $2s_0$. Such and still larger pressures can be reached in the contact areas. At these high pressures the ordinary friction rule cannot be true. It will be shown later how some of these difficulties can be avoided.

From tests on solid friction it is known that if the minutest quantities of a fluid are present which is wetting the surface of a solid, the coefficient of friction is lowered. Some kind of extreme-pressure lubrication in the contact areas of the rolls and the sheets must be postulated. It is therefore perhaps of practical interest to compare one or two further cases for the friction other than the one ($\tau = \mu p$) which is most frequently assumed, for which pressure curves are most easily obtained, namely:

(2) *Assume τ = Const.* In this case the pressure gradient becomes constant and the pressure lines $p = f(x)$ are straight lines.

(3) *Assume Viscous Friction.* When on the other hand a frictional resistance is considered which is proportional to the relative velocity of slip between the sheet and the pressure plates (rolls) and when the flow is symmetrical to the point $x = 0$, the shearing stress τ may be taken as

$$\tau = Cx \ldots\ldots\ldots\ldots\ldots\ldots [22]$$

This leads to conditions somewhat similar to those which were described for the compression of a viscous layer in section II(A) and to a pressure distribution

$$p = s_0 + (C/h)(a^2 - x^2) \ldots\ldots\ldots\ldots [23]$$

leading to a maximum pressure $p_{max} = s_0 + (Ca^2/h)$. Fig. 9 shows the pressure curves for these three cases: (1) dry friction, $\tau = \mu p$; (2) τ = const; and (3) viscous friction, $\tau = cu$ (u is the relative tangential velocity of flow along the compression

[6] "Untersuchungen über die Spannungsverteilung im Walzspalt," by E. Siebel and W. Lueg, *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung zu Düsseldorf*, vol. 15, 1933, Report No. 218, p. 1.

plates). It is assumed that the gradient of p is the same for $x = \pm a$.

(D) Distortion Due to Friction in Surface of Compressed Sheet

As mentioned in the introduction there is ample experimental evidence available that the outermost layers of a rolled or laterally compressed sheet can be considerably more distorted than the interior. The unit shearing strains γ_{xy} near the surface of the sheet can be considerably larger than in the central portions. An exact solution for a plane state of plastic strain by L. Prandtl[7] brings this out well and should therefore be recalled here. He found the following distribution of stress describing a flow of a material constrained between two parallel planes $y = \pm h/2$

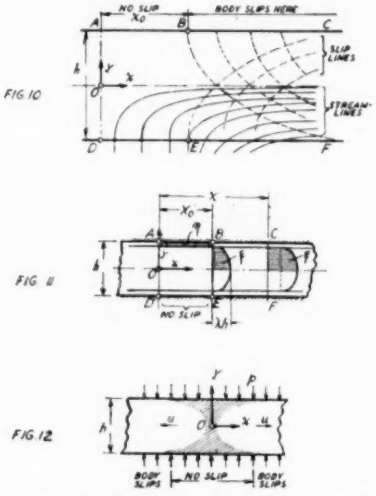
$$\left.\begin{aligned} \sigma_x &= C + s_0\left[\frac{x}{h} + \sqrt{\left(1 - \frac{4y^2}{h^2}\right)}\right] \\ \sigma_y &= C + (s_0 x/h) \\ \tau &= -s_0 y/h \end{aligned}\right\} \quad [24]$$

A family of cycloids (Fig. 10) as slip lines corresponds to this system of stresses. When $y = h/2$

$$\sigma_y = -p = C + (s_0 x/h), \quad \tau = -s_0/2 = \text{const.} \quad [25]$$

The same conditions are obtained which were mentioned in case (2). The gradient of the pressure dp/dx and the shearing stress τ in the plane $y = h/2$ remain constant. A system of plastic displacement components ξ, η which is consistent with Equations [24] has been given by the writer

$$\left.\begin{aligned} \xi &= \lambda\left[x - x_0 + h\sqrt{\left(1 - \frac{4y^2}{h^2}\right)}\right] \\ \eta &= -\lambda y \end{aligned}\right\} \quad [26]$$



To it corresponds a unit shear

$$\gamma = \frac{\partial \xi}{\partial y} + \frac{\partial \eta}{\partial x} = -\frac{4\lambda y}{h\sqrt{\left(1 - \frac{4y^2}{h^2}\right)}} \quad [27]$$

These last equations show how a plastic layer must deform under the stress system of Equations [24]. Straight lines, which were formerly perpendicular to the compression plates are distorted into semiellipses (Fig. 11). The unit shear γ increases rapidly with y and even becomes infinite in the planes $y = \pm h/2$.

The behavior of the solution in the neighborhood of these two planes $y = \pm h/2$ is extremely interesting from a mathematical point of view. These two parallel planes are not only natural boundary surfaces of the plastic body, but along them two distinct portions of the mathematical solution branch off from each other.[8] At any rate these details show that conditions with regard to adhesion and slip along the planes $y = \pm h/2$ cannot be quite simple when a plastic solid is forced to move in a tangential direction along a hard plate under a heavy pressure.[9] It is seen from Equation [26] that $\xi = 0$ when $x = x_0$, $y = h/2$, and the solid adheres at this point to the compression plate.

When the flow is symmetrical to a vertical axis another point should be mentioned. The preceding solution fails near the axis of symmetry. L. Prandtl and Hilda Geiringer[10] have drawn plausible extensions of the slip lines characterizing the trend of the solution in the central region of the compressed layer, which has been marked in Fig. 12 by shading. For reasons

Figs. 10, 11, and 12 Retarding Influence of Surface Upon Flow

of symmetry in this case τ must vanish in the axis $x = 0$. Hence a certain region $-x_0 < x < x_0$ must exist in the compressed sample, in which

$$-s_0/2 < \tau < s_0/2 \quad [28]$$

The writer believes that in this region the plastic solid adheres to the surface of the compression plates. As τ increases it becomes just equal to $s_0/2$ at a point x_0 and here the plastic solid starts to slip. This has been indicated in Figs. 10 and 11. In truth γ cannot become infinite, because of the strain hardening of the metal, which was here entirely neglected.

III ROLLING PRESSURES IN STRIPS UNDER SIMULTANEOUS PULLING

With reference to Fig. 13 representing a section through the rolls and the sheet let r be the radius of the working rolls, h the variable thickness of the sheet in the contact region, varying between the values of h_1 and h_2, x the horizontal distance of point A

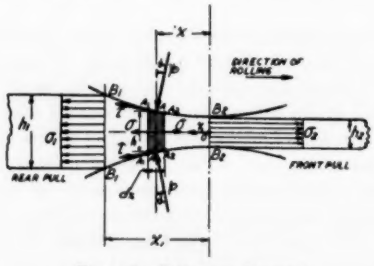


Fig. 13 Rolling Forces

in the sheet from the point O, x_1 the projected length of the contact arc B_1B_2, and α the angle between the normal to the rolls at point A and the vertical line passing through the roll centers.

[7] "Anwendungsbeispiele zu einem Henckyschen Satz über das plastische Gleichgewicht," by L. Prandtl, *Zeitschrift für angewandte Mathematik und Mechanik*, vol. 3, December, 1923,

[8] "Über die Gleit- und Verzweigungsflächen einiger Gleichgewichtszustände bildsamer Massen und die Nachspannungen bleibend verzerrter Körper," *Zeitschrift für Physik*, vol. 30, October, 1924, p. 106.

[9] Of interest in this regard is the paper, "The Distortion of Wires on Passing Through a Draw-Plate," by G. I. Taylor and H. Quinney, *Journal of the Institute of Metals*, vol. 49, 1932, p. 187. The authors have observed the distortion of wires after the drawing operation and their observations show this effect clearly.

[10] "Fondements Mathématiques de la Théorie des Corps Plastiques Isotropes," by Hilda Geiringer, Mémorial des Sciences Mathématiques, Paris, 1937, p. 76. Compare particularly her Fig. 15 on page 86 showing the flow lines.

Introducing for the reduction of thickness the notation

$$\lambda = (h_1 - h_2)/h_1 \quad [29]$$

and assuming small angles α for which

$$x/r = \sin\alpha = \alpha, \quad 1 - \cos\alpha = \alpha^2/2 = x^2/2r^2 \quad [30]$$

the variable thickness h can be taken as

$$h = h_2 + 2r(1 - \cos\alpha) = h_2 + r\alpha^2 = h_2 + (x^2/r) \quad [31]$$

and the length of the contact region becomes

$$x_1 = \sqrt{[r(h_1 - h_2)]} = \sqrt{(\lambda r h_1)} \quad [32]$$

Now let p be the surface pressure in lb per sq in. exerted at the points A by the roll on the deforming sheet, σ the mean value of the stress in the sheet in the rolling direction, τ the friction between rolls and sheet at the point A, and u the mean horizontal velocity with which the sheet moves when the cross section passes the point A at the distance x from O. The product of the mean velocity u of the sheet times the thickness h (volume of steel passing per second) is constant. Therefore

$$uh = u_1h_1 = u_2h_2 \quad [33]$$

where u_1 is the entering and u_2 the delivery velocity. From this it follows that the sheet must slip relatively to the roll with a velocity equal to $(u/\cos\alpha) - u_0$, where u_0 is the peripheral velocity of the rolls. Due to the smallness of the angles α this can also be taken equal to $u - u_0$. In the front portion of the contact zone where $u > u_0$ the sheet moves faster than the rolls (forward slip) and in the rear end of the pressure zone where $u < u_0$ the sheet moves slower than the rolls (backward slip).

Considering a small prism of material $A_1A_1A_2A_2$ (Fig. 13) of width dx and height h, the following forces act: On the top and bottom faces, the pressures $p\,dx$ normal to the surface of the rolls and the friction forces $\tau\,dx$ in a tangential direction (as long as $u > u_0$ these latter act on the sheet in the directions indicated in Fig. 13), and finally on the two side faces of the prism, the normal forces σh and $\sigma h + d(\sigma h)$ respectively. Equilibrium of the force components taken in the direction of rolling requires that

$$\frac{d}{dx}(h\sigma) + 2\tau + 2p\frac{x}{r} = 0 \quad [34]$$

Second, it is necessary to express that the sheet is deformed plastically. According to Equation 16 this is the case when

$$\sigma + p = s_0 \quad [34a]$$

where s_0 is the constrained yield strength as previously defined. Third a statement about the friction has to be made. Three different cases of friction will be considered again: (1) solid friction, $\tau = \pm\mu p$; (2) τ is constant; or (3) frictional resistance proportional to the relative velocity of slip between the sheet and the roll, if some kind of extreme-pressure lubricant be used. Before proceeding further the variables x and p are better transformed. Instead of the pressure p the ratio of p to the yield strength s_0 will be used as a new dependent variable $y = p/s_0$ and instead of the coordinate x (or the angle α) a new independent variable z defined by $x = \beta r z$, where the new dimensionless constant β is given by

$$\beta^2 = h_2/r = (1 - \lambda)h_1/r \quad [35]$$

This constant β depends on the ratio of the thickness to the radius of the roll. The variable thickness h which appears in Equation [34] can be expressed in terms of z using Equation [31] together with [35] which gives

$$h = h_2[1 + (x^2/rh_2)] = h_2(1 + z^2) \quad [36]$$

Taking Equations [35] and [36] and introducing

$$z = x/\beta r \text{ and } y = p/s_0 \quad [37]$$

Equation [34] is transformed to the following equation containing the new variables y and z

$$(1 + z^2)\frac{dy}{dz} - \left(\frac{2}{\beta s_0}\right)\tau = 2z \quad [38]$$

Of *this differential equation of the rolling problem*, which has figured in other forms in the papers by von Kármán, Siebel, Trinks, and Hitchcock, various applications will now be made. For this purpose the assumptions about the shearing stress τ expressing the resistance due to the surface friction of the rolls must be considered.

(1) Rolling Pressures With Solid Friction

Two branches of the pressure distribution have to be distinguished according to whether in the contact arc forward or backward slip occurs. In the first case $\tau = \mu p = \mu s_0 y$ and in the second case $\tau = -\mu p = -\mu s_0 y$. After writing for the constant $2\mu/\beta$

$$k = 2\mu/\beta = 2\mu\sqrt{[r/[(1 - \lambda)h_1]]} \quad [39]$$

Equation [38] becomes for forward slip

$$(1 + z^2)(dy/dz) - ky = 2z \quad [40]$$

This can be integrated after substituting instead of z a new variable v given by

$$z = \tan v, \quad dv = dz/(1 + z^2) \quad [41]$$

$$(dy/dv) - ky = 2\tan v \quad [42]$$

from which

$$y = e^{kv}(C + 2\int e^{-kv}\tan v\,dv) \quad [43]$$

is derived. In most cases this integral can be computed by replacing the term $\tan v$ by v and integrating.[11] This furnishes for the forward slip as the solution for the pressure curve

$$y = p/s_0 = C_2e^{kv} - 2(1 + kv)/k^2 \quad [44]$$

and for the backward slip

$$y = p/s_0 = C_1e^{-kv} - 2(1 - kv)/k^2 \quad [45]$$

After the integration constants C_1 and C_2 have been determined, rolling pressures can be computed from Equations [44] and [45]. It is noted that while the coordinate x varies between zero and $x_1 = \sqrt{(\lambda r h_1)}$ the variable z changes from the value zero to a value z_1 for which from Equations [32], [35], and [37]

$$z_1^2 = \frac{x_1^2}{\beta^2r^2} = \frac{\lambda h_1}{\beta^2 r} = \frac{\lambda}{1 - \lambda} \quad [46]$$

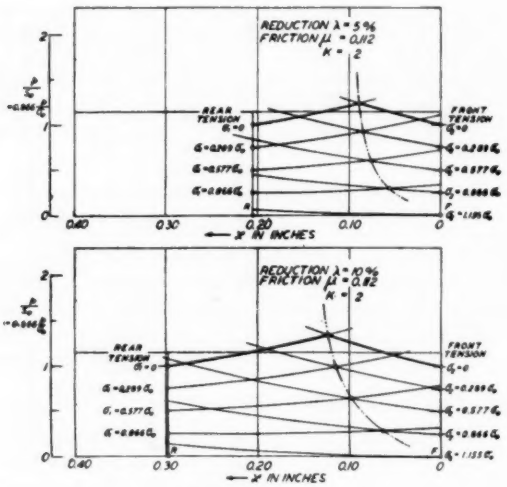
If for example the reduction in thickness is 50 per cent, $\lambda = 0.5$, $z_1 = 1$, and $0 < z < 1$. Usually $z_1 < 1$. The two integration constants C_1 and C_2 can be determined from the conditions at the ends of the contact zone so that the prescribed front and rear tensions σ_2 and σ_1 are reached there. From Equation [45] when

$$x = x_1; \quad z = z_1 = \sqrt{[\lambda/(1 - \lambda)]}, \quad \text{and } \sigma = \sigma_1 \quad [47]$$

and similarly from Equation [44] when

$$x = 0; \quad z = 0 \quad \text{and } \sigma = \sigma_2 \quad [48]$$

[11] The integrand could be expanded in a series writing $\tan v = v + v^3/3 + \ldots$ and the integration be carried out term by term. This series converges in the cases under consideration so rapidly that it is sufficient to take only the first term.



σ_1 is the specified back- and σ_2 the given front-tension stress in the rolled sheet. σ_1 acts at the entering and σ_2 at the delivery end of the pressure zone.

The rear and the front values of the pressure p_1 and p_2 are obtained from Equations [16] and [37] which also show that when using the conditions of Equations [47] and [48] we obtain when

$$z = z_1 = \sqrt{[\lambda/(1-\lambda)]}; \quad p_1 = s_0 - \sigma_1, \quad y_1 = 1 - (\sigma_1/s_0) \ldots [49]$$

and when $$z = 0; \quad p_2 = s_0 - \sigma_2, \quad y_2 = 1 - (\sigma_2/s_0) \ldots [50]$$

Conclusions. Summing up the results of the preceding analysis it is seen that the rolling pressures p can be computed as follows: Given are usually the sheet thickness h_1, the friction μ,

FIGS. 14 TO 21 ROLLING PRESSURES FOR VARIOUS AMOUNTS OF FRONT AND REAR TENSIONS

NOTATION FOR FIGS. 14 TO 21

(See Fig. 13)

p = pressure on roll surface, lb per sq in.
σ_1 = rear tension on strip, lb per sq in.
σ_2 = front tension on strip, lb per sq in.
σ_0 = yield stress in tension, lb per sq in.
μ = coefficient of friction
λ = $[(h_1 - h_2)/h_1] \times 100$, per cent (reduction)
h_2 = thickness of rolled sheet = 0.1 in.
r = radius of rolls = 8 in.
k = $2\mu\sqrt{(r/h_2)}$
s_0 = constrained yield strength, lb per sq in.

Ordinates, $p/s_0 = 0.866\ p/\sigma_0$

the radius of the rolls r, and the reduction λ. From these are computed the three constants

$$\beta^2 = (1 - \lambda)h_1/r, \quad z_1^2 = \lambda/(1 - \lambda), \quad k = 2\mu/\beta \ldots [51]$$

If the yield strength s_0 is known and the back and front tensions σ_1 and σ_2 are given, the back pressure $p_1 = s_0 - \sigma_1$ and the front pressure $p_2 = s_0 - \sigma_2$. Thus also $y_1 = 1 - (\sigma_1/s_0)$ and $y_2 = 1 - (\sigma_2/s_0)$. For a given distance x the roll pressure p is finally found after computing the parameters v and v_1

$$\tan v = x/\beta r, \quad \tan v_1 = \sqrt{[\lambda/(1 - \lambda)]} \ldots\ldots [52]$$

and p from either

$$p = s_0 \left\{ \left[y_1 + \frac{2(1 - kv_1)}{k^2} \right] e^{k(v_1 - v)} - \frac{2(1 - kv)}{k^2} \right\} \ldots [53]$$

or

$$p = s_0 \left[\left(y_2 + \frac{2}{k^2} \right) e^{kv} - \frac{2(1 + kv)}{k^2} \right] \ldots\ldots [54]$$

The first of these last pressure curves refers to the entering (rear) side of the sheet and the latter curve to the delivery (front) side. The smaller of the two values of p thus found has to be taken. It is noted that Equation [53] is valid when $x_0 < x < x_1$ and Equation [54] when $0 < x < x_0$, in which x_0 is the coordinate of the "neutral point" at which the friction changes its direction. The value x_0 is defined by the intercept of curves [53] and [54] referring to the pressures in the rear and front portions of the pressure area respectively.

Using these expressions a few pressure distributions $p = f(x)$ have been computed numerically[12] and the results plotted in Figs. 14 to 21. Three cases have been chosen, assuming a small, medium, and large friction coefficient $\mu = 0.112$, 0.224, and 0.448 respectively. The following reductions of thickness were compared: $\lambda = 5$, 10, 20, and 30 per cent.

The delivery thickness $h_2 = (1 - \lambda)h_1$ of the sheet was $h_2 = 0.1$ in., the radius of the rolls was $r = 8$ in. The abscissas in the figures represent the coordinate x or the distance of a point from the center line of the rolls. The ordinates show the corresponding roll pressures in the contact zone. The ratios p/s_0 were plotted. The three cases of normal, medium, and large friction correspond to a value for the constant k of 2, 4, and 8 respectively. The direction of sheet travel in all pressure plots is from the left to the right. The top pressures shown with heavy lines correspond to the case when the rear and front tensions are zero. In each diagram additional pressure lines are indicated, corresponding to a rear or a front tension equal to σ_1 or $\sigma_2 = 0.289\,\sigma_0$, $0.577\,\sigma_0$, and $0.866\,\sigma_0$. Thus by interpolating between these curves, intermediate pressure lines may be constructed for other values of the front or rear tensions. The pressure hills are the steeper the larger the friction is and they become less steep with increasing front or rear tension. The neutral point shifts its position toward the delivery side or in the direction of sheet travel when both the front and the rear tension simultaneously increase in the same proportion. On the contrary the neutral point is shifted in an opposite direction when the front tension increases more than the rear tension. These conclusions may be useful for estimating the forward slip in the sheets passing under the rolls after a change in front or rear pull has occurred.

(2) Rolling Pressures When Surface Friction Is Assumed Constant

Let the surface friction be designated by τ (lb per sq in.). According to whether $z < z_0$ (forward slip) or $z > z_0$ (backward slip), $\tau = \tau_0$ or $\tau = -\tau_0$. After writing for the combination of constants

$$2\,\tau_0/\beta s_0 = k \ldots\ldots [55]$$

Equation [38] becomes

$$\frac{dy}{dz} = \pm \frac{k}{1 + z^2} + \frac{2z}{1 + z^2} \ldots\ldots [56]$$

This differential equation of rolling, integrated for the pressure, gives the function

$$y = p/s_0 = \pm k \tan^{-1} z + \ln(1 + z^2) + C \ldots\ldots [57]$$

The upper and lower signs are to be taken for forward and backward slip respectively. Assuming no front and no rear tension the integration constants become

$$C_1 = 1 \text{ and } C_2 = 1 + k \tan^{-1} z_1 - \ln(1 + z_1^2) \ldots [58]$$

These pressure curves are shown in Fig. 22 in an example in which it is assumed that the surface friction is one tenth of the constrained yield strength s_0, that the ratio of the roll radius to the sheet thickness h_1 is 100, and that a reduction of 50 per cent is taken. Thus $\tau = 0.1 s_0$, $r/h_1 = 100$, and $\lambda = 0.5$. This gives $\beta^2 = h_2/r = 0.00500$, $\beta = 0.0707$, $z_1 = 1$ and $k = 2.829$.

(3) Rolling Pressures When the Surface Friction Is Assumed Proportional to the Relative Velocity of Slip

It was mentioned that little is known about the friction when lubricated sheets are rolled. In cold reducing of very thin sheets palm oil is used as a lubricant. The viscosity of oils is known to decrease with temperature, but to increase with the pressure p. According to recent tests by R. B. Dow[13] increasing the pressure by 10,000 lb per sq in. increases the viscosity of mineral oils about ten times. Viscosity of oils η seems to increase with the pressure according to an exponential function of p. It is certain therefore that η in an oil layer or in the patches of oil which may be present in the areas carrying such high pressures as are known to exist during the rolling of very thin steel sheets, must be of quite another order of magnitude than at atmospheric pressure. Although observations are not available to substantiate the following assumption, which is rather doubtful in its present shape, it was thought that it might at least be interesting to inquire what will become of the pressure hill and what shape the pressure line $p = f(x)$ will take if the tangential surface forces be assumed proportional to the relative velocity of slipping in the contact area.[14] The constant which expresses this proportionality may contain η and the thickness δ of the oil layer. For η may be taken a mean value of the viscosity at the high rolling pressures. Whether a continuous oil layer can exist or whether the oil is only present in patches with a varying δ must be left an open question. Let u_0 be the peripheral velocity of the roll and u the variable velocity of translation with which the sheet moves in the contact zone. Since the variable thickness is

$$h = h_2 (1 + z^2) \ldots\ldots [58a]$$

the velocity is

$$u = u_2 h_2/h = u_2/(1 + z^2) \ldots\ldots [59]$$

and the velocity of the slip is equal to $u - u_0$. Since

[12] The author acknowledges the valuable assistance received in these computations by Mr. Frankenberg.

[13] "The Effects of Pressure and Temperature on the Viscosity of Lubricating Oils," by R. B. Dow, *Journal of Applied Physics*, vol. 8, 1937, p. 367.

[14] Also, this assumption cannot be based on experimental information. It is rather more probable that the law $\eta = \text{const}$ is not applicable at high pressures and in very thin films of oil but that $\tau = f(\partial\gamma/\partial t)$.

$$u_0 = u_2/(1 + z_0^2) \quad [59a]$$

where z_0 is the (unknown) value of z corresponding to the point at which the slip is zero, the friction law which was postulated can be expressed by the equation

$$\tau = \frac{\eta}{\delta}(u - u_0) = \frac{\eta u_2}{\delta}\left(\frac{1}{1+z^2} - \frac{1}{1+z_0^2}\right) \quad [60]$$

in which δ may be interpreted as a kind of mean thickness of the

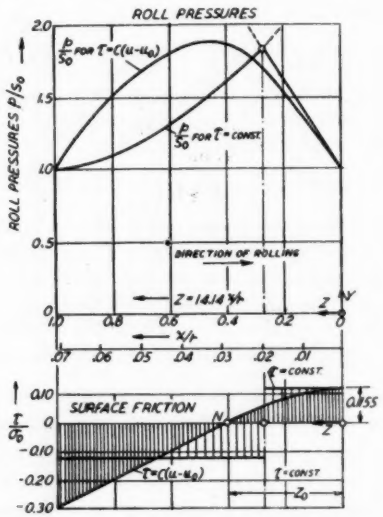

FIG. 22 DISTRIBUTION OF ROLLING PRESSURE AND SURFACE FRICTION CORRESPONDING TO TWO ASSUMPTIONS FOR FRICTION ($\lambda = 0.5$, no front or back tension, $r/h_1 = 100$, $r = 10$ in.)

oil film. After replacing $\eta u_2/\delta$ which has the dimension of a shearing stress by the symbol τ_0 and using

$$k = 2\tau_0/\beta s_0 \quad [60a]$$

the surface friction between roll and sheet can be written as

$$\tau = \tau_0\left(\frac{1}{1+z^2} - \frac{1}{1+z_0^2}\right) \quad [61]$$

and the differential equation of rolling [38] becomes

$$(1+z^2)\frac{dy}{dz} = k\left(\frac{1}{1+z^2} - \frac{1}{1+z_0^2}\right) + 2z \quad [62]$$

The ambiguous $\pm$ sign has now entirely disappeared from the equation and with it the need of distinguishing two distinct branches of pressure lines which complicated the former discussions. It is also noted that if $z = z_0$, $dy/dz \neq 0$, the neutral point does not coincide with the location of the maximum in the pressure hill as one would have perhaps guessed. After carrying out the integration of Equation [62] the following pressure distribution is found (when no tensions act)

$$y = \frac{p}{s_0} = 1 + \ln(1+z^2) + \frac{k}{2}\left[\frac{z}{1+z^2} - \left(\frac{1-z_0^2}{1+z_0^2}\right)\tan^{-1}z\right] \quad [63]$$

The variable z in this function is related to the distance x by $x = \beta r z$, where the constant $\beta^2 = h_2/r$. The pressure distribution given by Equation [63] satisfies the condition that for $z = 0$, $y = 1$. Similarly at the other end of the pressure zone, where $z = z_1$, y must also become equal to 1. This latter condition

$$z = z_1 = \sqrt{[\lambda/(1-\lambda)]}, \qquad y = 1 \quad [64]$$

really defines the location of the neutral point (the coordinates z_0 or x_0) and the forward slip in the sheet

$$\nu = (u_2 - u_0)/u_0 \quad [65]$$

As according to Equation [59a] $u_2 = u_0(1 + z_0^2)$, it is seen that the *forward slip* becomes equal to

$$\nu = z_0^2 \quad [66]$$

That the forward slip must increase when a lubricant is acting follows from Fig. 22 by comparing the two curves for τ corresponding to the two cases (2) and (3).

Fig. 22 shows the rolling pressures for this case in an example in which the same data were assumed as in the last example: $r = 10$ in., $h_1 = 0.10$ in., $h_2 = 0.050$ in., $\lambda = 0.5$, apparent friction coefficient at delivery point $\mu = 0.1$. Under these conditions $\beta = 0.0707$ and $z_1 = 1$. The length of the contact zone is $x_1 = \beta r z_1 = 0.707$ in. The distance x_0 for the neutral point is $x_0 = 0.283$ in. corresponding to $z_0 = 0.40$. Fig. 22 shows both the pressures p and the distribution of the surface frictions τ.

It is hoped that the various examples which have been worked out in detail will prove of some assistance to rolling-mill engineers until more experimental information becomes available with regard to the fairly complex conditions under which the thickness of metal sheets is reduced in mills.

ACKNOWLEDGMENTS

Acknowledgments are due to L. W. Chubb, director of the Westinghouse Research Laboratories, for the possibility of carrying out this work, to G. E. Stoltz, manager, steel mill department and P. G. Lessmann, both of the Westinghouse Electric & Manufacturing Co. in East Pittsburgh, for supporting these investigations and for much valuable information received from them on rolling, and to F. C. Biggert, vice-president of the United Engineering & Foundry Co. in Pittsburgh for his interest in this subject.

Numerical and Graphical Method of Solving Two-Dimensional Stress Problems

By H. PORITSKY[1] and H. D. SNIVELY,[2] SCHENECTADY, N. Y., and C. R. WYLIE, JR.,[3] COLUMBUS, O.

In developing his numerical and graphical method for solving two-dimensional stress problems, while the authors use a tension member with a semicircular notch as an example, the procedure actually has a wide range of application. Comparison of the calculated results and those obtained from photoelasticity shows close agreement. The maximum value of the stress in the plate used as an example obtained by this method is 3.25. This compares with a maximum of 3.20 obtained photoelastically by Wahl and Beeuwkes and a maximum of 3.05 obtained in the same manner by M. M. Frocht.

THE PURPOSE of this paper is to develop a method of solving two-dimensional stress problems. While the procedure is illustrated on a tension member with a semicircular notch, Fig. 1, it is very general in its applicability.

1 *Introduction.* A comparison of the calculated results with those obtained from photoelasticity showed very good agreement indeed. While the expense of carrying out a calculation by the present method compares favorably with that of photoelastic analysis, the method is still somewhat lengthy.

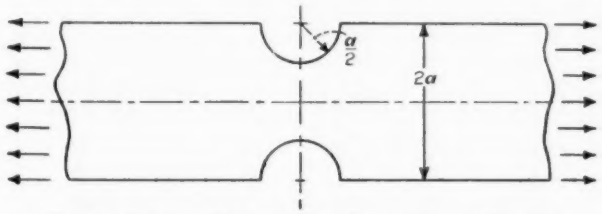

FIG. 1 TENSION MEMBER WITH SEMICIRCULAR NOTCHES

It will be recalled that plane-stress distributions may be expressed in terms of Airy's function F, which satisfies the differential equation

$$\nabla^4 F = (\nabla^2)^2 F = \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)^2 F = \left(\frac{\partial^4}{\partial x^4} + 2\frac{\partial^4}{\partial x^2 \partial y^2} + \frac{\partial^4}{\partial y^4}\right) F = 0 \quad \ldots\ldots [1]$$

In terms of F the stresses are given by

$$X_x = \frac{\partial^2 F}{\partial y^2}, \quad X_y = -\frac{\partial^2 F}{\partial x \partial y}, \quad Y_y = \frac{\partial^2 F}{\partial x^2} \quad \ldots\ldots [2]$$

The problem of determining the stresses which arise in a simply connected region from the application of given tractions over the boundary C, leads to a solution F of Equation [1] with prescribed values of F and of $\partial F/\partial n$, the normal derivative of F, along C.

Equation [1] is also of interest in connection with *bending* or *transverse* deflections of thin plates, in which case it is satisfied by the normal deflection over regions free from normal load. The boundary conditions prescribing F and $\partial F/\partial n$ correspond to displacing the edge of the plate and forcing a proper slope.

2 *Finite Differences.* The method of solution makes use of finite-difference approximations. First and second derivatives, such as du/dx, $\frac{d^2u}{dx^2}$, are approximated, respectively, by the following quotients

$$\frac{du}{dx} = \frac{u(x+\delta) - u(x)}{\delta} \quad \ldots\ldots [3]$$

$$\frac{d^2u}{dx^2} = \frac{u(x+\delta) - 2u(x) + u(x-\delta)}{\delta^2} \quad \ldots\ldots [4]$$

whose limits, as δ approaches zero, yield the true derivatives. Likewise the Laplacian ∇^2 is replaced by

$$\nabla^2 F = \frac{F(x+\delta,y) + F(x-\delta,y) + F(x,y+\delta) + F(x,y-\delta) - 4F(x,y)}{\delta^2} = 4(F_m - F)/\delta^2 \quad \ldots\ldots [5]$$

where F_m is the mean of the values of F at the four points obtained by adding or subtracting it from x or y of the point in question, Fig. 2.

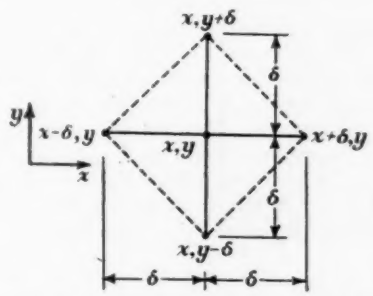

FIG. 2 REGION USED FOR FINITE-DIFFERENCE APPROXIMATION

Introducing a square lattice by cutting the region by means of the two sets of lines $x = x_i$, $y = y_j$ each a distance δ apart, and replacing Equation [1] by

$$s = \nabla^2 F, \ \nabla^2 s = 0 \quad \ldots\ldots [6]$$

causes departure from Equation [6] to

$$(F_{i+1,j} + F_{i-1,j} + F_{i,j+1} + F_{i,j-1}) - 4F_{i,j} = \delta^2 s_{i,j} \quad \ldots [7]$$

$$(s_{i+1,j} + s_{i-1,j} + s_{i,j+1} + s_{i,j-1}) - 4s_{i,j} = 0 \quad \ldots\ldots [7a]$$

where $F_{i,j} = F(x_i, y_j)$ and similarly for s_{ij}. In this way Equa-

Presented at the Joint Meeting of the Applied Mechanics and Hydraulic Divisions of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, Ithaca, N. Y., June 25–26, 1937.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until August 10, 1939, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

tion [1] is replaced by a finite number of equations in a finite number of unknowns s_{ij}, F_{ij}.

If C is a rectangle of sides $m\delta$, $n\delta$, and if the boundary values of F and s are prescribed, then there are $2(m-1)(n-1)$ Equations [7] and [7a] for an equal number of variables. However, for other regions or boundary conditions complications arise at the boundaries. These could to some extent be overcome by

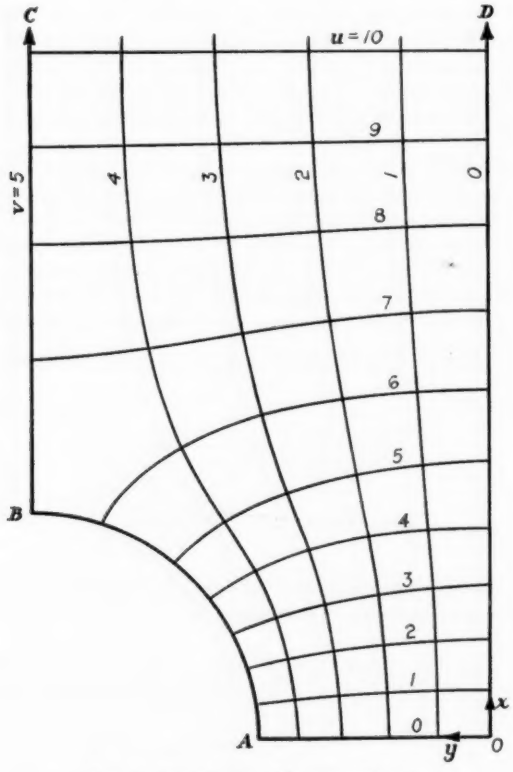

FIG. 3 CONFORMAL MAP, x, y-PLANE

using differences of values of s, F corresponding to unequal spacing of either x or y, but only at the expense of introducing much more complicated coefficients. This is avoided to a large extent by "mapping" the region inside C "conformally" on a rectangle, infinite strip, or some other simple region of another plane, say the u, v-plane. In general it is necessary to resort to a free-hand plot for this purpose. Thus Fig. 3 shows a conformal map of a quarter of the region of Fig. 1 on the corresponding strip of the u, v-plane. The boundary ABC of Fig. 3 has been "straightened out" into $v = 5$ in Fig. 4. It may be shown that in terms of the new variables Equation [6] is replaced by

$$\nabla^2_{u,v} F = s/r^2 \quad \ldots\ldots [8]$$

$$\nabla^2_{u,v} s = 0 \quad \ldots\ldots [8a]$$

where r is the ratio of element of length in the u, v-plane to the corresponding element of length in the x, y-plane

$$r = \frac{\text{side of (very small) square in the } u, v\text{-plane}}{\text{side of corresponding square in the } x, y\text{-plane}}.$$

The value of r is most conveniently found by plotting curves of x and y versus u, measuring the slopes $\partial x/\partial u$ and $\partial y/\partial u$, and utilizing the relation

$$r^2 = \frac{1}{(\partial x/\partial u)^2 + (\partial y/\partial u)^2} \quad \ldots\ldots [9]$$

Values obtained from Equation [9] should be checked by plotting x and y versus v and using

$$r^2 = \frac{1}{(\partial x/\partial v)^2 + (\partial y/\partial v)^2} \quad \ldots\ldots [10]$$

If the conformal plot is good the values obtained by Equations [9] and [10] will be essentially identical.

Equations [8] and [8a] can now be approximated by the difference equations

$$(F_{i+1,j} + F_{i-1,j} + F_{i,j+1} + F_{i,j-1}) - 4F_{i,j} = \delta^2 s_{i,j}/r^2_{i,j} \quad [11]$$

$$(s_{i+1,j} + s_{i-1,j} + s_{i,j+1} + s_{i,j-1}) - 4s_{i,j} = 0 \quad \ldots\ldots [11a]$$

At the boundaries, say at v = constant, no equation similar to Equations [11] and [11a] can be used, since this would involve values of F or s outside the region. Here $\nabla^2_{u,v} F = s/r^2$ is approximated by

$$\frac{s}{r^2} = \frac{\partial^2 F}{\partial u^2} + \frac{2}{\delta^2}\left[F_1 - F_0 + \delta\left(\frac{\partial F}{\partial v}\right)_0\right] \quad \ldots\ldots [12]$$

where subscript $_0$ indicates boundary values and subscript $_1$ indicates values at a distance δ from the boundary, while

$$\left(\frac{\partial F}{\partial v}\right)_0 = -\frac{1}{r}\left(\frac{\partial F}{\partial n}\right)_{x,y} \quad \ldots\ldots [13]$$

The last term of Equation [12] is obtained by using a second-degree polynomial through F_0, F_1, F_2; the preceding term of Equation [12], $\partial^2 F/\partial u^2$, is found best by plotting the boundary F against u, since the second difference method was not found sufficiently exact on the boundary.

3 *Solution by Successive Improvement.* To solve the resulting equations directly by determinants or elimination proved too difficult, since for 5×12 squares in the u, v-plane there are nearly 120 equations in 120 variables (counting the s- and F-values).

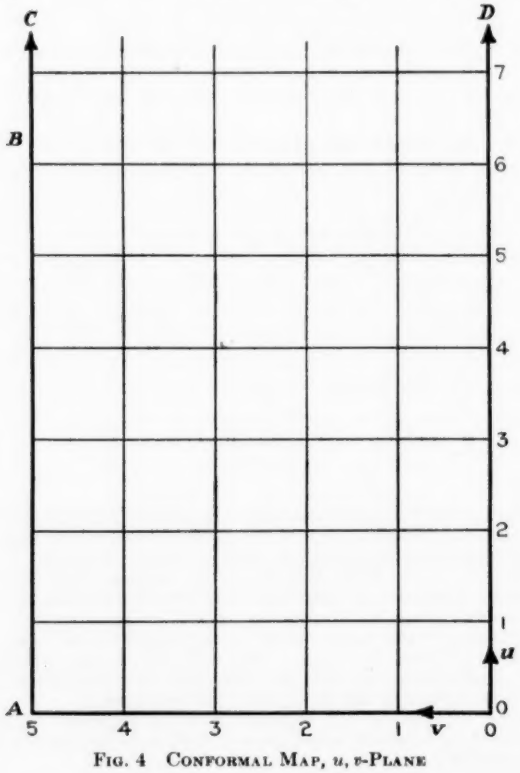

FIG. 4 CONFORMAL MAP, u, v-PLANE

Only in case of a square where there is symmetry about two perpendicular axes so that only one eighth of the region need be considered, is it at all advisable to use direct solution (1).[4] An indirect method was tried consisting in writing Equations [11] and [11a] in the form

$$s_{i,j} = \text{mean of four surrounding } s\text{-values} \ldots\ldots [14]$$

$$F_{i,j} = -\frac{\delta^2 s_{i,j}}{4r^2} + \text{mean of four surrounding } F\text{-values} \quad [14a]$$

starting with an intelligent guess at s and F, and improving it by substituting the guessed values on the right-hand side of Equations [14] and [14a] and using the resulting values of s, F as new values. These new, presumably improved, values were again substituted on the right side of Equations [14] and [14a], obtaining the next improvement or approximation, and so forth. A similar treatment is also given to Equation [12].

Methods similar to the foregoing have been reported by A. Thom and have been used by him successfully for the determination of the flow of ideal fluids (this reduces to the Laplace equation), for viscous fluids (2, 3) and for the problem of torsion of circular shafts of varying radius (4). In the case of the viscous fluid the differential equations involve repeated Laplacian as well as nonlinear combinations of lower derivatives. It was Thom's work, in fact, that suggested this method to the authors.

An attack was made on a plane-stress problem along these lines, but it proved unsuccessful. Even after repeating the successive improvements twelve and more times, there was no indication of convergence to a limiting set of values. Whether Thom's success lay in unreserved man power or whether it had to do with the nonlinearity of the problem—a feature which in general hampers classical methods of solution—the authors have never discovered. Perhaps the slowness of convergence has to do with the fact that the process of taking a mean of the four surrounding values reaches out only a distance δ, while its repetition reaches out over a square of larger size. One would expect that if convergence takes place at all, it would take place only after these squares have expanded over several times the size of the region, so that the "reflected wave fronts" have passed through each point several times. Now these wave fronts creep slowly, advancing only a step δ with each repetition of the process; thus it becomes apparent that many repetitions, indeed, are required before convergence is obtained.

The convergence was studied by considering solutions of $d^2s/dx^2 = 0$ (the Laplace equation in one dimension) and seeing how many repetitions were required to obtain convergence in simple cases. As many as 55 repetitions were required to secure 90 per cent accuracy. Various modifications were tried on the one-dimensional case. The results which proved successful were incorporated in the method finally adopted.

4 *Modifications Introduced to Secure Convergence.* One modification introduced in the method described in section 3 consisted in using *continuous corrections*. Instead of using all the *old* values of F in the right-hand members of Equations [14] and [14a] as many of the *corrected* values as have been obtained are used there. Thus the effect of a change in the boundary values is felt at once everywhere (though not to the full extent away from the boundary). The correcting process was begun at $u = 12$, $v = 3$, and from there proceeded inward to $v = 0$, and then inward along $u = 11, 10, \ldots\ldots 1, 0$, in turn.

The second modification introduced consisted in solving the Laplace Equation [8] for s exactly, the strip being a region for which such an exact solution in terms of boundary values is possible. For the strip

$$-\frac{h}{2} < v < \frac{h}{2}$$

if the boundary values of s are symmetric about $v = 0$, it may be shown that

$$s(u, v) = \frac{\cos\frac{\pi v}{h}}{h} \int_{-\infty}^{\infty} \frac{s(u') \cosh\frac{\pi}{h}(u' - u)}{\cosh^2\frac{\pi}{h}(u' - u) - \sin^2\frac{\pi}{h} v}\, du' \ldots [15]$$

where $s(u')$ represents boundary values of s. This integral was evaluated by the trapezoidal rule. Similarly, for a rectangle, the exact solution for s in terms of boundary values is possible, although the place of Equation [15] is taken by integrals involving elliptic functions. Thus the s-equations of Equation [14] were dispensed with completely, an exact solution for the s-values being given by Equation [15].

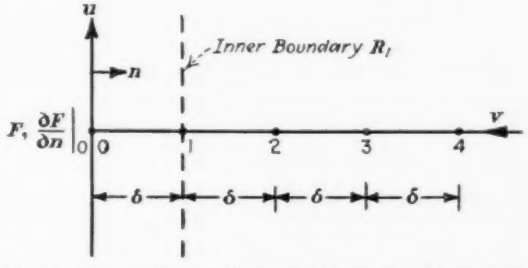

FIG. 5 POINTS USED IN APPLYING BOUNDARY CONDITIONS

The third modification of the original procedure consisted in eliminating the s-values along the boundary of the strip from the various stages of the calculations. The boundary values used for s in applying Equation [15] were taken to be those at points a distance δ from the true boundary, lying on two lines R_1 a distance δ from the true boundary R. Not until the final set of values of F and s was obtained over R_1 were the boundary values of s over R found. We shall refer to R_1 as the "inner boundary."

In addition to diminishing the number of s-values that had to be found at each stage of the successive approximations, the elimination of the boundary values is of advantage in that concentrations of stress at the boundary result there in rapid variations of s, so that the finite difference approximations are not sufficiently accurate. As is known, any irregularities or discontinuities in boundary values of a harmonic function are rapidly smoothed out away from the boundary.

Finally a change was introduced in connection with the manner of improving both F and s over the inner boundary R_1. Instead of using Equation [8] or its approximation Equation [14a] for improving F, it was used for improving s after the F-values had been improved. The new F-values along R_1 were then determined by passing a third-degree polynomial through the boundary value F_0 and having the given slope $\partial F/\partial v|_0$ there and through the two recently improved values F_2 and F_3 just inside the inner boundary R_1 Fig. 5. The value of F at R_1 as given by this polynomial turns out to be

$$F_1 = \frac{1}{18}\left(11F_0 + 9F_2 - 2F_3 - 6\left.\frac{\partial F}{\partial v}\right|_0 \delta\right) \ldots\ldots [16]$$

It is this method of improving the inner boundary values of F that forces the solution to fit both known boundary conditions. A third-degree polynomial was chosen rather than a second-degree, because of somewhat better accuracy, since it reaches further into the inside.

[4] Numbers in parentheses refer to the Bibliography at the end of the paper.

Thus modified, the procedure turned out to be completely successful. After the s- and F-values on and within R_1 had converged to proper limits, $\nabla^2 F$ was evaluated at the boundary R. Using the polynomial referred to in the foregoing, it is found that

$$\left.\frac{\partial^2 F}{\partial v^2}\right|_0 = \frac{1}{18}\left(-19F_0 + 27F_2 - 8F_3 + 30\left.\frac{\partial F}{\partial v}\right|_0 \delta\right) \ldots [17]$$

$$= 2F_0 - 5F_1 + 4F_2 - F_3 \ldots\ldots\ldots\ldots [18]$$

The component $\left.\frac{\partial^2 F}{\partial u^2}\right|_0$ of ∇^2 was evaluated graphically. The following checks should be made on the values thus determined. First, the boundary values of s must form a smooth curve when they are plotted against the tangential coordinate; second, each value must agree well with the value obtained by extrapolating the curves of the inner s-values to the boundary; third, the values must be such that the relation $\nabla^2 s = 0$ is satisfied.

5 *Summary of the Procedure Employed*. The procedure outlined may be summarized as follows:

a By means of a small square graphical plot make a conformal transformation from the original shape of Fig. 1 to a strip and determine r^2 at the corners of all the small squares.

b Calculate the values of F and its inner normal derivative, corresponding to all the corners of squares which fall on the boundary.

c Assume a set of F-values at all of the inner corners of squares. This should be as good a guess as possible.

d From the assumed F-values, calculate the s-values at all points on the inner boundary R_1 by means of the relation $\nabla^2_{u,v} F = s/r^2$, or rather its approximating Equation [14*a*].

e By means of Equation [15], determine the values of s at all points within R_1 so that $\nabla^2 s = 0$ is satisfied in this region.

f Correct all the values of F within the inner boundary by means of the numerical approximation to $\nabla^2_{u,v} F = s/r^2$, using continuous corrections such as described.

g Correct the F-values along R_1 by means of Equation [16].

h From the newly determined set of F-values, obtain another set of values of s along R_1.

i Repeat steps *a* to *h* until the F- and s-values converge.

j Determine graphically or numerically the actual boundary values of s in accordance with the relation $\nabla^2_{u,v} F = s/r^2$ and check these values by the methods which are described at the end of section 4.

6 *Results*. Table 1 gives the values of the free boundary stresses, while Fig. 6 shows a plot of these stresses for one quarter of the member itself.

The maximum value of the stress obtained by this method is 3.25. This compares with a maximum of 3.20 obtained photoelastically by Wahl and Beeuwkes (5), and a maximum of 3.05 obtained photoelastically by M. M. Frocht (6).

TABLE 1 VALUES OF FREE BOUNDARY STRESSES

u	0	1	2	3	4	5	6
s	3.25	3.15	3.00	2.80	2.15	1.05	0.10
u	7	8	9	10	11	12	
s	0.10	0.60	0.85	0.90	0.95	0.99	

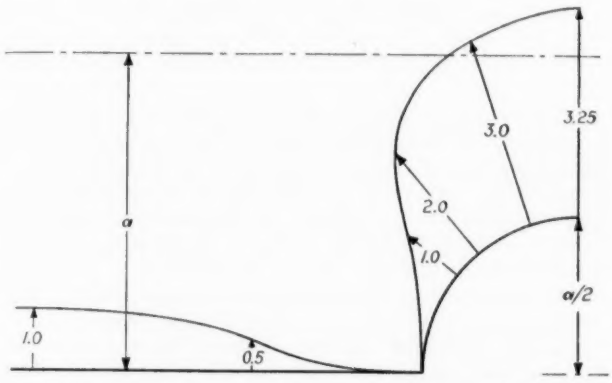

FIG. 6 FREE BOUNDARY STRESSES IN NOTCHED MEMBER

The method was also used in determining the stresses in a loaded T-head dovetail joint and in particular for investigating the effect of the size of the fillet upon the stress-concentration factor of these dovetails. In this case the dovetail region was conformally mapped upon a rectangle. The exact determination of inner values of the harmonic function s was not made by Equation [15] but by a somewhat similar expression involving elliptic functions. The final numerical results thus obtained were in excellent agreement with photoelastic results.

A Method of Calculating Energy Losses During Impact

By C. ZENER[1] and H. FESHBACH[2]

When an elastic sphere collides with another perfectly elastic body, part of the initial kinetic energy is lost in starting elastic waves in the two bodies. The energy thus dissipated can be calculated by previous analytical methods only when it is a small fraction of the initial kinetic energy. This paper develops an approximate analytical method for this calculation which is applicable even when the greater part of the energy is dissipated. Thus in a particular case where the energy dissipated is 90 per cent of the original kinetic energy, an error of only 0.7 per cent is made. The new element in this analysis is the introduction of a "normalized" interaction force which is necessarily quite insensitive to one's ignorance of the exact interaction force.

The powerfulness of the method is illustrated by a complete survey of the problem of impact of spheres with beams fixed at each end. Graphs are constructed showing the variation of the coefficient of restitution with the length of the beam and the mass of the sphere. Impacts with multiple blows are excluded. It is found that when the mass of the sphere is kept constant, the coefficient of restitution has a minimum for a certain optimal beam length, and is independent of the beam length for values greater than twice the optimal length. The coefficient is a minimum when the period of the fundamental mode of vibration is approximately equal to 2.4 times the time of contact.

The method is also applied to the impact of spheres with large thin plates. The semiempirical formula of Raman is derived.

Although this analytical method cannot be applied to impacts with multiple blows, it nevertheless gives the conditions for such multiple blows.

Introduction

THE EXACT theory for the collision of two elastic bodies has been developed only for two extreme cases. In the first,[3] contact between the two bodies is established instantaneously and likewise ceases instantaneously. These conditions are satisfied in the longitudinal collision of two bars with ideally smooth plane surfaces. In this case, the two bodies are treated as a single elastic body after the establishment of contact. The process of collision is studied by merely following the propagation of a discontinuous elastic wave. In such collisions a large part of the original kinetic energy may be transformed into vibrational energy. In the second case,[4] the time required to establish maximum contact is very long compared to the time required for an elastic wave to traverse the length of the two bodies. This condition is satisfied in the collision of two spheres with small relative velocity of approach. In this case the strains are localized to the vicinity of the contact region. The force F which each body exerts on the other is then a function only of the distance of approach ξ after contact is first established. The variation of ξ with time is then determined by Newton's second law. The total kinetic energy of the two bodies is unaltered by such a collision.

All actual collisions are of an intermediate type. The time required for the establishment of maximum contact is finite, but only under special conditions is it long compared to the time required for an elastic wave to traverse both of the colliding bodies. The exact treatment of such a collision leads to an integrodifferential equation. An investigation of this equation has shown that under certain conditions a single impact consists of a series of distinctly separated blows.[5] The mere labor involved in solving this integrodifferential equation has, however, unfortunately prevented finding how the loss of kinetic energy depends upon the various parameters of a collision. There is thus a need for an approximate method by means of which the effect of the various collision parameters can be studied. Such a method is developed in this paper for the collision of spheres with other bodies. Its usefulness is demonstrated by a complete survey of the problem of the collision of a sphere with a beam fixed at both ends. Finally, by means of this method the solution is obtained for the collision of a sphere with large plates.

General Theory

The duration of an impact of a sphere with another body is so long, compared to the period of the fundamental mode of the sphere, that the elastic vibration of the sphere absorbs only a negligible fraction of the initial kinetic energy.[6] Thus it is only necessary to calculate the energy ΔE absorbed by the body which the sphere strikes. This energy is completely determined by the force $F(t)$ which the sphere exerts upon this body. This force has been calculated by Hertz for the particular case where the strains are localized to the immediate vicinity of the region of contact. It will be denoted by $F_H(t)$. In more general cases a gross error would be introduced by replacing the actual force by the Hertz force.

Fully realizing our ignorance of the force $F(t)$, we nevertheless proceed in the standard way to evaluate the energy absorbed by an elastic body acted upon by the force $F(t)$. In our final expression for ΔE, we shall then make a simple transformation

which renders ΔE exceedingly insensitive to errors in $F(t)$. The power of this transformation can be appreciated by comparing the calculated ΔE with the ΔE obtained by Timoshenko[5] by the numerical solution of the exact integrodifferential equation for a special case. In this example, the error in ΔE obtained by replacing $F(t)$ by $F_H(t)$ is reduced by this transformation from 160 per cent to less than 0.7 per cent, the rebound velocity of the sphere is obtained with an error of less than 3 per cent.

The differential equation for an elastic body acted upon by a force with volume density $\boldsymbol{f}(\boldsymbol{r}, t)$ is given by

$$(\partial^2/\partial t^2)\boldsymbol{U} = L\boldsymbol{U} + \rho^{-1}\boldsymbol{f} \quad \ldots\ldots\ldots\ldots\ldots [1]$$

Here $\boldsymbol{U}(\boldsymbol{r},t)$ is the vector displacement function, L a linear differential operator of the second order, and ρ is the mass density. We expand $\boldsymbol{U}$ in terms of the normalized eigenfunctions $\boldsymbol{U}_k(\boldsymbol{r})$ of the differential equation

$$(L + \omega_k^2)\,\boldsymbol{U}_k = 0$$

and of the boundary conditions appropriate to the problem. Upon substitution of this expansion

$$\boldsymbol{U}(\boldsymbol{r}, t) = \Sigma C_k(t)\,\boldsymbol{U}_k(\boldsymbol{r})$$

into Equation [1], multipling on the left by $\boldsymbol{U}_n$, and integrating over the entire solid, we obtain

$$[(\partial^2/\partial t^2) + \omega_n^2]C_n = \rho^{-1} f_n(t)$$

where $f_n(t) = \int \boldsymbol{f}\cdot\boldsymbol{U}_n d\boldsymbol{v}$. Before collision all the C's and their first time derivatives are zero. The solution of these equations subject to this boundary condition is

$$C_n(t) = (1/\omega_n\rho)\int_{-\infty}^{t} \sin\omega_n\,(t - t')f_n(t')dt' \quad \ldots\ldots [2]$$

The energy of elastic vibration is given by the equation

$$\Delta E = (\rho/2)\Sigma_n[(\partial C_n/\partial t)^2 + \omega_n^2 C_n^2] \quad \ldots\ldots\ldots\ldots [3]$$

The energy absorbed after the collision is now obtained by substituting Equation [2] into Equation [3], and setting $t = \infty$. First, however, we shall transform the function f_n. The force density $\boldsymbol{f}$ due to the impact is confined to a very small region. All the eigenfunctions $\boldsymbol{U}_k$ may be regarded as constant in this region except those with very high ω. But for these the corresponding C's after collision are negligibly small.[6] Hence we may write $f_n(t) = \delta_n F(t)$, where δ_n is equal to the component of $\boldsymbol{U}_n$ normal to the surface at the region of contact, and $F(t)$ is the magnitude of the total force, i.e., $F(t) = \left|\int \boldsymbol{f} d\boldsymbol{v}\right|$. We thus obtain for the energy absorbed after the collision

$$\Delta E = (1/2\rho)\Sigma_n\delta_n^2\left|\int_{-\infty}^{\infty} F(t)e^{i\omega_n t}\,dt\right|^2$$

We shall now endeavor to remove as far as possible errors resulting from our ignorance of the force $F(t)$. From Newton's third law, $-F$ is the force which acts upon the sphere. Hence $-\int F dt$ is equal to the change in momentum of the sphere. If m is the mass of the sphere, v its initial velocity, and ev its final velocity in the opposite direction, then the change of momentum is $-mv(1 + e)$, i.e., $\int F(t)dt = mv(1 + e)$. We may thus write $F(t)$ as $F(t) = mv(1 + e)\mathfrak{F}(t)$, where $\mathfrak{F}$ is the normalized force

$$\mathfrak{F}(t) = F(t)\Big/\int_{-\infty}^{\infty} F(t)dt.$$

Denoting by E the initial energy of the sphere $mv^2/2$ we obtain $\Delta E/E = (1 + e)^2 R$, where

$$R = m\rho^{-1}\Sigma_n\delta_n^2\left|\int_{-\infty}^{\infty}\mathfrak{F}(t)e^{i\omega_n t}\,dt\right|^2$$

Our difficulties have now largely disappeared. In the first place, we may eliminate the unknown coefficient of restitution e by means of the equation $\Delta E/E = 1 - e^2$, obtaining

$$\Delta E/E = 4R/(1 + R)^2 \quad \ldots\ldots\ldots\ldots\ldots [4]$$

Conversely, we may eliminate $\Delta E/E$, obtaining

$$e = (1 - R)/(1 + R) \quad \ldots\ldots\ldots\ldots\ldots [5]$$

In the second place, the quantity R is comparatively insensitive to errors in the force $F(t)$. This is so since the integrands of R contain explicitly only the function $\mathfrak{F}(t)$ which has been so defined that the integral $\int_{-\infty}^{\infty}\mathfrak{F}(t)dt$ is independent of the function $\mathfrak{F}(t)$. Only the shape of $\mathfrak{F}(t)$ is thus subject to error.

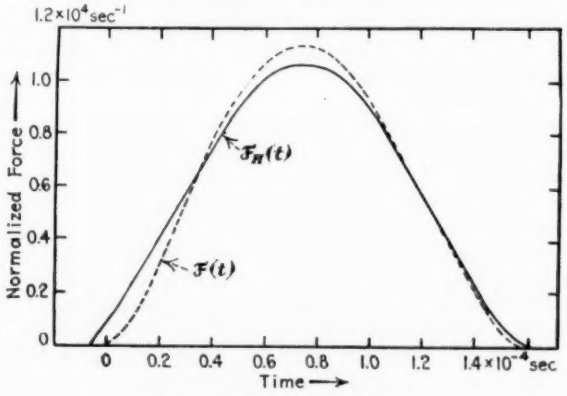

FIG. 1 NORMALIZED FORCES

(The broken curve is the normalized exact force for the particular example studied by Timoshenko. The full curve is the normalized Hertz force for the same example. In this example 90 per cent of the initial energy of the sphere is lost during collision.)

As evidence that the shape of $\mathfrak{F}(t)$ is little different from the shape of the normalized Hertz force

$$\mathfrak{F}_H(t) = F_H(t)\Big/\int_{-\infty}^{\infty} F_H(t)\,dt$$

we compare in Fig. 1 these two functions for the particular example for which $F(t)$ has been exactly calculated by Timoshenko.[5] Although in this particular example the sphere loses more than 90 per cent of its energy during collision, nevertheless $\mathfrak{F}_H(t)$ differs only slightly from $\mathfrak{F}(t)$. It is thus to be expected that only a very slight error will be made by substituting the first function for the second, excluding of course the case of multiple collisions. Such multiple collisions will occur whenever the calculated e is negative.

We have now the problem of evaluating the integrals in R, with $\mathfrak{F}(t)$ replaced by $\mathfrak{F}_H(t)$. This is most readily done by finding an analytical function which closely approximates $\mathfrak{F}_H(t)$. We have found the following function satisfactory

$$\begin{aligned} &[1 + \cos(2\pi t/T)]/T \quad \text{for} \quad -T/2 < t < T/2 \\ &0 \quad\qquad\qquad\quad \text{for} \quad |t| > T/2 \end{aligned}$$

in which T is adjusted so that the maximum of this function $2/T$ is equal to the maximum of $\mathfrak{F}_H(t)$. It may readily be shown that

TABLE 1 COMPARISON OF NORMALIZED HERTZ FORCE WITH ANALYTICAL APPROXIMATION $T = 1.0873\ T_H$

(The origin of time is taken as the instant of closest approach)

t/T_H	0	0.05	0.10	0.15	0.20	0.25	0.30	0.35	0.40	0.45	0.50	0.5438
$\mathfrak{F}_H(t) \times T_H$	1.839	1.802	1.694	1.523	1.303	1.051	0.785	0.525	0.291	0.104	0	0
$T^{-1}[1 + \cos(2\pi t/T)]T_H$	1.839	1.801	1.690	1.515	1.291	1.036	0.771	0.519	0.299	0.132	0.029	0

the maximum of $\mathfrak{F}_H(t)$ is $1.8395/T_H$, where T_H is the Hertz time of collision. Hence $T = 1.0873\ T_H$. The close agreement of this function with $\mathfrak{F}_H(t)$ is shown in Table 1.

Each integral in R is a function only of the one parameter $Q_n = \nu_n T$, $\nu_n = \omega_n/2\pi$, which is the number of oscillations of the nth mode in the time T. The percentage error in the integrals introduced by replacing $\mathfrak{F}_H(t)$ by this function is appreciable only for those integrals for which Q_n is large compared to unity. But these integrals are so small that their contribution to R is negligible. In this way we obtain

$$R = m\rho^{-1}\Sigma_n \delta_n^2 \left[\frac{\sin(\pi Q_n)}{\pi Q_n(Q_n^2 - 1)}\right]^2 \quad \ldots\ldots\ldots\ldots [6]$$

We have now obtained explicit formulas for $\Delta E/E$, Equation [4], and for e, Equation [5], in terms of a single parameter R. This parameter in turn is given by Equation [6] in terms of the displacement δ_n and frequency ν_n, of each normal mode of vibration, and in terms of the Hertz time of collision T_H. This time of collision may be calculated from the equation[3]

$$T_H = 10.97\left[\frac{(m')^2(E_1 + E_2)^2}{v r^2 E_1^2 E_2^2}\right]^{1/5} \quad \ldots\ldots\ldots\ldots [7]$$

where m' is the reduced mass of the two bodies. It is equal to the mass of the sphere alone if the struck body is supported at its boundaries. Also v is the initial velocity of the sphere; E_1 is the ratio of Young's modulus over $1 - \sigma_1^2$, where σ_1 is the Poisson ratio of the sphere; and E_2 refers to the corresponding quantity for the struck body. If the surface of the struck body is plane, r is the radius of the sphere. More generally, it refers to $r_1 r_2/(r_1 + r_2)$, where r_1 and r_2 are the radii of curvature of the two surfaces.

Application to Collisions of Spheres With Beams

In this section we apply the results of the previous paragraph to the collision of a sphere with a beam pivoted at both ends, with the impact being at the middle of the beam.

The normalized displacement functions for a beam pivoted at both ends are $U_n = (2/V)^{1/2}\sin(n\pi x/L)$, $n = 1, 2, 3\ldots$. Here V is the volume of the beam, L its length. The value of the displacement function at the point of contact, $x = L/2$, has been denoted by δ_n. In this case $\delta_n^2 = 2/V$ with n odd, and $\delta_n = 0$ with n even. The frequency ν_n of the nth mode is related to the frequency of the first by $\nu_n = n^2\nu_1$. Upon substituting these relations into Equation [6], we obtain

$$R = (2m/M)\sum_{n=0}^{\infty}\left\{\frac{\sin[(2n+1)^2\pi Q_1]}{(2n+1)^2\pi Q_1[(2n+1)^4 Q_1^2 - 1]}\right\}^2$$

Here m and M refer to the mass of the sphere and beam, respectively. As Q_1 approaches zero, the summation approaches infinity as $Q_1^{-1/2}$. It is thus convenient to write R in the form $R = (m/MQ_1^{1/2})G(Q_1)$, where

$$G(Q_1) = 2\,Q_1^{1/2}\sum_{n=0}^{\infty}\left\{\frac{\sin[(2n+1)^2\pi Q_1]}{(2n+1)^2\pi Q_1[(2n+1)^4 Q_1^2 - 1]}\right\}^2$$

Values of this function are given in Table 2.

TABLE 2

Q_1	$G(Q_1)$	Q_1	$G(Q_1)$	Q_1	$G(Q_1)$
0	0.840	0.25	0.922	1.0	0.500
0.02	0.840	0.30	0.976	1.1	0.378
0.04	0.840	0.35	1.008	1.2	0.278
0.06	0.840	0.40	1.028	1.3	0.205
0.08	0.846	0.45	1.032	1.4	0.123
0.10	0.832	0.50	1.018	1.5	0.078
0.12	0.814	0.55	1.000	1.6	0.038
0.14	0.803	0.60	0.972	1.7	0.010
0.16	0.810	0.7	0.880	1.8	0.002
0.18	0.824	0.8	0.766	1.9	0.000
0.20	0.850	0.9	0.632	...	...

We can now obtain at once $\Delta E/E$ and e for any set of collision parameters. Q_1 is given in terms of the fundamental frequency ν_1 of the beam, and the Hertz time of collision T_H by

$$Q_1 = 1.087\nu_1 T_H$$

or in terms of the mass, radius, and initial velocity of the sphere, m, r, and v, respectively, by

$$Q_1 = 11.93\,\nu_1\left[\frac{m^2(E_1 + E_2)^2}{rvE_1^2E_2^2}\right]^{1/5}$$

From Table 2 we now obtain the function $G(Q_1)$. Finally, by substituting R into Equations [4] and [5] we obtain the fractional energy loss $\Delta E/E$ and the coefficient of restitution e, respectively.

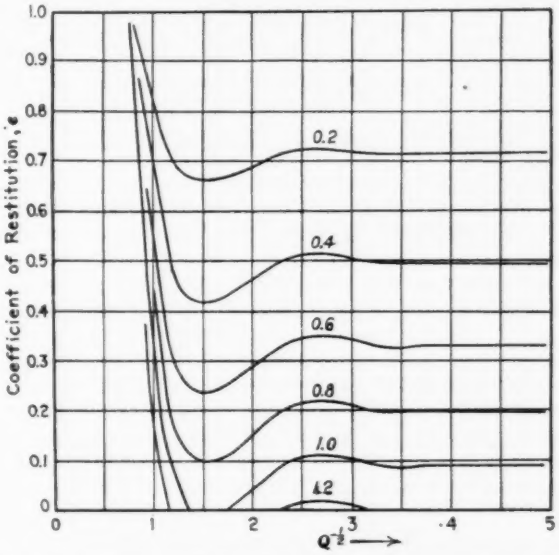

Fig. 2 Coefficient of Restitution of a Sphere Colliding With a Beam Pivoted at Both Ends
(The label on each curve refers to the ratio $m/MQ_1^{1/2}$.)

The fundamental frequency ν_1 and hence also Q_1, varies inversely as the square of the beam length. Hence the variation of e with beam length is best illustrated, as in Fig. 2, by plotting e as a function of $Q_1^{-1/2}$ for various values of the parameter $m/(MQ_1^{1/2})$, which is independent of the beam length. At $Q_1 = 0.45$, the value of e has a deep minimum corresponding to a fundamental period 2.4 times as long as the Hertz time of collision. The value of e is nearly independent of beam length for lengths greater than twice the optimal length. The variation of e with the mass of the sphere m is obtained by passing from one curve to another, with a slight change in the scale of the abscissa. This change of scale is due to the fact that $Q_1^{-1/2}$ is proportional to $m^{-1/5}$.

As a check upon our approximate method, we shall find the e and $\Delta E/E$ for that particular case for which Timoshenko[4] numerically solved the exact integrodifferential equation. In this example the necessary data are: $\nu_1 = 1000$, $T_H = (8/45) \times 10^{-3}$, $(m/M) = 0.273$. We obtain $Q_1 = 0.193$, and hence from Table 2 $G(Q_1) = 0.840$, $R = 0.521$, and finally $e = 0.314$. This calculated e is 3 per cent higher than Timoshenko's value 0.305. Our calculated fractional energy loss $\Delta E/E = 1 - e^2 = 0.901$ is thus 0.7 per cent lower than that obtained by Timoshenko. Timoshenko also examined a case in which the collision consisted of a series of blows. The parameters $Q_1^{-1/2}$ and $m/MQ_1^{1/2}$ for this case are 3.0 and 3.3, respectively. Reference to Fig. 2 shows that our calculated e is negative, and hence the collision must be multiple.

Application to Collisions of Spheres With Large Thin Plates

In this section we apply the general results of general theory to the collision of spheres with large plates. We shall take the plate to be circular with a radius R much larger than its thickness. Then the normalized displacement functions are given by

$$U_n = J_0(k_n r) \Big/ \left[4\pi h \int_0^R J_0^2(k_n r) r dr \right]^{1/2}, \quad n = 1, 2 \ldots\ldots$$

Corresponding to the condition that U_n vanish at the boundary, k_n is the nth root of $J_0(kR) = 0$. Corresponding to the condition that the point of contact be at the center of the plate, δ_n is given by the value of U_n at $r = 0$. For large values of R this gives $\delta_n^2 = k_n/4hR$. The assumption that R is large enables us to replace the summation in Equation [6] by an integration. Since consecutive k's differ by π/R, the summation sign is replaced by $(R/\pi)\int_0^\infty dk_n \ldots\ldots$ Upon using the following relation[7] between k_n and ν_n

$$k_n^2 = (2\pi/h)(3\rho/E_2)^{1/2} \nu_n$$

where E_2 is the same elastic constant as used in the last section, we obtain

$$R = \left(\frac{m}{4\pi h^2 T}\right)\left(\frac{3}{\rho E_2}\right)^{1/2} \int_0^\infty \left[\frac{\sin \pi Q}{\pi Q(Q^2 - 1)}\right]^2 dQ$$

$$= [3m/(16\pi h^2 T)]\,[3/(\rho E_2)]^{1/2}$$

In order to conform to the notation of Raman,[8] we replace T by $1.087\, T_H$, and introduce the symbol

$$k = \pi h^2 T_H (\rho E_2/3)^{1/2} = 19.90 h^2 (\rho E_2)^{1/2} \left\{ \frac{m^2(E_1 + E_2)^2}{v r E_1^2 E_2^2} \right\}^{1/5}$$

Upon substituting R into Equation [5], we obtain finally

$$e = (k - 0.542m)/(k + 0.542m)$$

This equation is identical to the equation which Raman[8] gave as fitting his experimental data, save that his numerical coefficient was 0.56 in place of 0.542. The accuracy of his data is not sufficient to distinguish between these two coefficients. Raman obtained his formula by choosing, ad hoc, that wave form in the plate which gave the best agreement with experiment. The experiments disagree with the theoretical formula for values of e less than about $1/_2$.

Calculation of Stresses Within the Boundary of Photoelastic Models

By R. WELLER[1] and G. H. SHORTLEY,[2] COLUMBUS, OHIO

A method is proposed for the determination of the internal stresses in a two-dimensional system from data furnished by a photoelastic analysis. The method involves the numerical integration of the Laplace difference equation over a region with known boundary values by the iteration of a set of improvement formulas. The underlying theory is discussed briefly, reference being made to a more mathematical treatment appearing in another paper by the authors. New procedures for increasing the speed and accuracy of such computations are described and application is made to a typical photoelastic study. In this the complete system of internal stresses is computed, using the data obtained from the usual fringe photograph, without recourse to isoclinic lines, or other supplementary experimental measurements. The method is also applicable to other problems of potential theory which involve the vanishing of the Laplacian. This includes electric fields, steady-state heat conduction, shapes of membranes, and problems in hydrodynamics and gravitation.

THE METHODS which have been previously used for the determination of the internal stresses in a two-dimensional stress system from photoelastic data have been very laborious and in many cases inaccurate. These internal stresses have been obtained by graphical methods which make use of the isoclinic-line families,[3,4] methods depending on the measurement of thickness deformation,[5] the membrane analogy,[6] and direct interferometer methods. In this paper the authors will describe a procedure for obtaining these stresses by numerical integration directly from the boundary stresses. In this procedure no data are required beyond those given by the usual fringe photograph. The accuracy of the method is limited only by the accuracy with which the boundary stresses may be obtained from this photograph. No great skill is required in carrying out the computations. It is believed that the time and labor involved are much less than for other methods.

In the following discussion, the application of this method to a typical photoelastic problem will be described and a brief statement concerning the underlying theory will be made. However, most of the subject matter will be devoted to the technique of operation. A detailed treatment of the mathematical properties of the functions involved, together with data concerning rates of convergence, accuracy of results, etc., has been published in another paper by the authors.[6]

It is shown in any treatise on the theory of elasticity[7] that the sum of the principal stresses S_1 and S_2, in a two-dimensional stress system obeys the Laplace differential equation

$$\frac{\partial^2(S_1 + S_2)}{\partial x^2} + \frac{\partial^2(S_1 + S_2)}{\partial y^2} = 0$$

To solve this equation in a given region, the values of $(S_1 + S_2)$ along the boundary of the region are required. These are conveniently obtained from the fringe photograph at points which are not subject to external forces, since at a free boundary the principal stress directions are normal and tangential, the normal stress being zero. Hence on a free boundary, the sum of the principal stresses equals the difference between the principal stresses, which latter the fringe photograph gives directly. The stress at parts of the boundary where loads are applied cannot be evaluated in this way. In such cases boundary values suitable for use with Laplace's equation may be obtained by an approximate analytical treatment and the use of St. Venant's principle. Frequently for purposes of calculation, it is desirable to use an artificial boundary which avoids loaded parts of the actual boundary, obtaining approximate analytical values of the stresses along the artificial boundary. The same treatment of loaded boundaries is used in the membrane analogy.

The Liebmann Procedure

The Laplace equation can be solved analytically in only a few trivial cases since, in the general case of an irregular boundary, systems of separable coordinates cannot be found. However, an approximation to the solution may be obtained by solving the so-called Laplace difference equation in place of the differential equation.[8] In using the difference equation, proceed by laying down a square network on the region to be treated. Then consider the values of $(S_1 + S_2) = \psi$ only at the corners of the net, rather than at every point within the region. The difference equation requires that the value of ψ at any point in such a square net be the average of its values at the four nearest neighboring points. Let Fig. 1 represent a region in which a function ψ is to satisfy the Laplace difference equation and hence satisfy the differential equation approximately. It is assumed that the boundary values of ψ are known and may be written down at points where the net intersects the boundary. The requirement that the value of ψ at each interior point be the average of its four nearest neighbors gives a set of nine linear equations for the nine interior values of ψ. A typical equation of this set is

$$\psi_T = \frac{1}{4}(\psi_X + \psi_V + \psi_Z + \psi_K)$$

In general there are as many equations of this type as there are interior points of the net; too many equations to attempt to solve directly. Liebmann[9] has suggested a convenient iterative procedure for solving these equations for the unknown values of ψ at the interior points. At the beginning of this procedure entirely arbitrary values are assumed, based on whatever experience the individual may have had in such matters. The more nearly these assigned values approach the correct ones, the more rapid will be the convergence of the iterative procedure. However, any finite assigned values whatever will lead to the correct result.

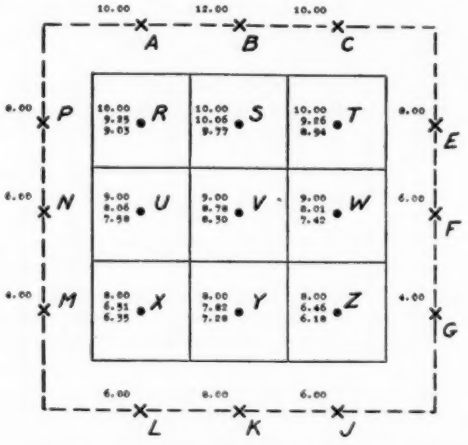

FIG. 1 SMALL NET ILLUSTRATING THE USE OF THE SIMPLE LIEBMANN IMPROVEMENT FORMULA

(Actual points of the net are shown as small black circles. The solid lines are so drawn as to form squares around each of the net points. This enables the writing down of all numbers relating to any particular point inside a single square, thus avoiding confusion as to which point is designated by any one number. Boundary points at which the function values are assumed to be known are indicated by crosses.)

The procedure is then to replace each value by the average of the four nearest neighbors, going over the set of points in some definite order, say alphabetically from R to Z in Fig. 1. The result of this operation is a new set of values for all points except those on the boundary. These values furnish a closer approximation to the true solution than the original arbitrary values. A second traverse over the net will yield a still better approximation, and so on. This should be repeated until the values reproduce themselves at each point to the required number of significant figures. Then it will be observed that the final values satisfy the difference equation. For example in Fig. 1, a column of numbers is associated with each point inside the net and a single number with each boundary point. Assume that the boundary values are given. The top number at each of the interior points is a value arbitrarily assigned. The second number in the column represents the value obtained by the first traverse over the set of points. In calculating the improved value at a given point, the previously altered values are used whenever they are available. Thus in the first traverse

$$9.25 = \frac{1}{4}(8 + 10 + 10 + 9) \qquad \text{(point } R\text{)}$$

$$10.06 = \frac{1}{4}(9.25 + 12 + 10 + 9) \qquad \text{(point } S\text{)}$$

$$8.01 = \frac{1}{4}(8.78 + 9.26 + 6 + 8) \qquad \text{(point } W\text{), etc.}$$

[9] "Die Angenaherte Ermittelung Harmonischer Funktionen und Konformer Abbildungen," by H. Liebmann, Sitzungberichte der Bayerischen Akademie der Wissenschaften zu München, Mathematische Physikalische Klasse, 1918, p. 385.

The third number at each point results from a second traverse. Further traverses would soon result in the appearance of stationary values, thus providing the solution of the Laplace equation within the given region to four significant figures.

The foregoing process is called the Liebmann procedure after its discoverer. A brief discussion together with a proof of convergence is given by Frank and von Mises.[10] It may be applied without modification to stress problems if desired, although the authors have developed a modified procedure which results in much more rapid convergence.

BOUNDARY POINTS

In the case of a point which is not equidistant from its four nearest neighbors, the simple improvement formula is not applicable. Fig. 2 shows such a point. In this case there are two

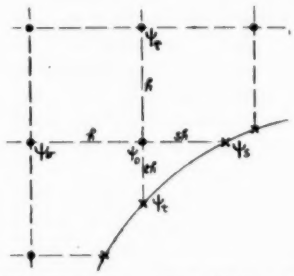

FIG. 2 TREATMENT OF A POINT NEAR A BOUNDARY, SEE EQUATION [1]

neighbors which lie at distances which are less than the net spacing h. The formula for the improved value of ψ_0 at this point is

$$\psi_0' = \frac{st}{s+t}\left[\frac{1}{1+t}\psi_r + \frac{1}{1+s}\psi_\sigma + \frac{1}{t(1+t)}\psi_t + \frac{1}{s(1+s)}\psi_s\right] = c_r\psi_r + c_\sigma\psi_\sigma + c_t\psi_t + c_s\psi_s \quad [1]$$

The values s and t here represent fractions of the normal net spacing. Note that $c_r + c_\sigma + c_t + c_s = 1$; this may be used as a check of these coefficients. In setting up the problem, the values of the coefficients c may be calculated once for all and written down on the net. In particular, since the two points at odd distances are almost always boundary points and hence do not change in value as the iteration is carried on, the product of the coefficients and values may be computed and written on the net. These points will be illustrated later in detail by treatment of a particular example (see Fig. 9).

A procedure has thus been described which may be used to solve problems in stress distribution, as follows:

1 Determine the stress values along the model boundary (or an artificial boundary) by the usual photoelastic method.

2 Lay down a square network on the model.

3 Evaluate by interpolation the points where the net intersects the boundary.

4 Apply the improvement formulas given until the values at each point reproduce themselves.

In applying this procedure to a practical problem, the fineness of the net which is to be employed must be considered, since the accuracy with which the solution of the difference equations agrees with that of the differential equation is increased by refining the net; but so is the amount of labor required to solve the difference equations. A criterion of accuracy is furnished by the use of two nets of different fineness over the same region, the second having one half the spacing of the first. If the values of ψ

[10] "Differential und Integral Gleichungen der Mechanik und Physik," by P. Frank and R. von Mises, Friedrick Vieweg and Son, Berlin, 1930, part 1, p. 735.

obtained from the two nets differ by less than three times the permissible error, the value from the finer net is satisfactory, since the error is approximately proportional to the square of the net spacing. A net with intervals one half as great as those of a previous net will converge to a value having an error with respect to the true continuous solution of Laplace's equation of about one fourth as much as that of the coarser net. It is advisable always to start by solving the difference equations with a very coarse net having, say ten to fifteen interior points. Then in successive steps cut the net spacing in half until the desired fineness is attained. The previous solutions of the coarser nets are desirable because, at each halving of the net constant, the convergence is about four times as slow. Hence it is economical of time to get as good a function as possible from a coarse net to use as the initial trial function for the finer net, in order to keep the error in the trial function as small as possible.

The use of the procedure described will result in a rather slow rate of convergence when a net of considerable fineness is employed. The means by which the convergence may be speeded up will be discussed later. The behavior of the nets and of how a consideration of this behavior leads to improvement in their treatment will now be discussed briefly.

Elementary Theory

The initial arbitrary values assigned to the interior points of a net may be considered as a set of numbers which constitutes the true solution of the difference equations plus an undetermined error at each interior point. It is clear that the use of an improvement formula does not change the true solution, but merely causes it to reproduce itself. The effect of the improvement operation is simply to reduce the amount of the error with each traverse over the net. The amount of reduction depends on the shape of the function representing the error. If the error is smooth and pillow-shaped, it will not sink very rapidly, but any roughness or jaggedness will disappear very quickly. It is possible to find certain error functions which, when improved, will be reduced to a constant fraction of themselves without being changed in shape. Such a function is called an eigenfunction of the improvement process. These functions, of course, have zero boundary values. The different eigenfunctions are denoted by $\phi^{(1)}, \phi^{(2)}, \phi^{(3)}, \ldots$ On improvement these go over to

$$\phi^{(1)\prime} = \lambda_1\phi^{(1)} \qquad \phi^{(2)\prime} = \lambda_2\phi^{(2)} \ldots$$

The λ values (eigenvalues) will all be less than unity, and one of them, say λ_1 will be the largest. It is now possible to make a sort of Fourier expansion of the actual error function ϕ in terms of the eigenfunctions, i.e.

$$\phi = a_1\phi^{(1)} + a_2\phi^{(2)} + a_3\phi^{(3)} + \ldots . \qquad \ldots\ldots\ldots (2)$$

On improvement this becomes

$$\phi' = a_1\lambda_1\phi^{(1)} + a_2\lambda_2\phi^{(2)} + a_3\lambda_3\phi^{(3)} + \ldots$$

After n improvements, the eigenfunctions will have been reduced by λ_k^n and soon all the functions of lower eigenvalue will disappear, leaving only a constant times $\phi^{(1)}$. The rate of convergence of the procedure depends upon the rate at which $\phi^{(1)}$ disappears, which in turn depends on λ_1. After the iteration has been carried on for a number of traverses, the error begins to be reduced at a uniform rate, each traverse reducing it by the same fraction λ_1.

Table 1 gives values of λ_1 for the ordinary Liebmann procedure taken over a square area with various numbers of intervals p, along the sides. This gives some idea as to the dependence of the rate of convergence upon the fineness of the net. For large p, $1 - \lambda_1 = \pi^2/p^2$.

For example, the error at any point in a square region with ten intervals on a side, that is, with 81 interior points, is reduced to about nine tenths of itself by each traverse after it has been improved a few times. At this rate it would take about 23 traverses

TABLE 1

p	λ_1
3	0.250
4	0.500
6	0.750
10	0.9045
18	0.9698

to reduce the error to one tenth of its initial value. For a net of eighteen intervals about 75 traverses would be necessary, etc. Later it will be seen, how, by extrapolation, the number of necessary traverses can be reduced to a fraction of these figures, even for the Liebmann procedure.

Symmetry

The treatment of a symmetrical model is much simpler than that for a nonsymmetrical one. If the original net is laid down so that a line of points lies along an axis of symmetry, these points may be improved in the usual way by assuming that values on opposite sides of the line are equal and are improved simultaneously. Thus, in Fig. 1 the line through B and K is a line of symmetry. The point at V is then improved by the following formula

$$4\psi'_V = \psi_S + 2\psi_U + \psi_Y$$

and only one half of the area need be treated. Each time R is improved, for example, T may be considered to have been improved at the same time. It is of course necessary that both the model contour and the loading system be symmetrical in order to have a symmetrical stress system. In the case of a fine net, the labor of calculation is roughly cut in half by each axis of symmetry. Lines of symmetry need not lie parallel to the principal directions of the net but they may equally well lie at 45 deg to it.

Multiple-Point Methods

The rate of convergence may be greatly increased by improving the points a block at a time rather than singly. For example consider Fig. 3, in which the internal points have been divided

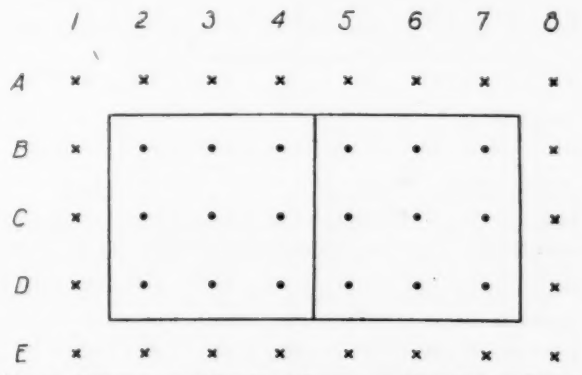

Fig. 3 Division of a Net Into Groups of Nine Points Each

into two square arrays of nine each. The borders of these groups are indicated by heavy lines. Consider the block for which $C3$ is the center point. A simultaneous solution of the set of nine equations, which express the requirement that the value at each of these points be the mean of its four neighbors, gives the following formula which may be used in calculating the improved value of the center point of the block directly from the boundary values

$$\psi'_{C3} = \frac{1}{16}\Big[2(\psi_{A3} + \psi_{C5} + \psi_{E3} + \psi_{C1}) + \psi_{A2} + \psi_{A4} + \psi_{B5} + \psi_{D5} + \psi_{E4} + \psi_{E2} + \psi_{D1} + \psi_{B1}\Big] \quad \ldots\ldots\ldots [3]$$

Having the center point, the four corner points may be improved by diagonal application of the single-point formula

$$\psi'_{B2} = \frac{1}{4}(\psi'_{C3} + \psi_{C1} + \psi_{A1} + \psi_{A3})$$

$$\psi'_{B4} = \frac{1}{4}(\psi'_{C3} + \psi_{C5} + \psi_{A5} + \psi_{A3})$$

$$\psi'_{D4} = \frac{1}{4}(\psi'_{C3} + \psi_{C5} + \psi_{E3} + \psi_{E5})$$

$$\psi'_{D2} = \frac{1}{4}(\psi'_{C3} + \psi_{C1} + \psi_{E1} + \psi_{E3})$$

In these formulas the improved value of ψ_{C3} is used. The five improved values now available may be used for the improvement of points $B3$, $C4$, $D3$, and $C2$ in the usual way, e.g.,

$$\psi'_{B3} = \frac{1}{4}(\psi'_{B2} + \psi_{A3} + \psi'_{B4} + \psi'_{C3})$$

This provides a procedure by means of which a network such as that of Fig. 3 may be improved much more rapidly than by the single-point treatment. The left block is improved as described and then the right block, improving first the center point $C6$ and subsequently the others. In the event that a nine block lies adjacent to a boundary or, if for any other reason the value of $A1$, say, is not available, the point $B2$ may be improved by the formula

$$\psi'_{B2} = \frac{1}{8}(2\psi'_{C3} + \psi_{A3} + \psi_{C1} + 2\psi_{A2} + 2\psi_{B1})$$

in place of the formula just given.

The value of λ_1 for this procedure will be less than that for the Liebmann process, indicating a more rapid rate of convergence. Table 2 gives values for the nine-block method of improvement. In this case, for large p, $1 - \lambda_1 = 3.5\pi^2/p^2$. For any value of p, the number of traverses, yielding a given error reduction with the nine-block procedure, is reduced over the single-point method by a factor of about 3.5, which results, in most practical problems, in a very satisfactory rate of convergence.

TABLE 2

p	λ_1
7	0.503
10	0.712
16	0.874
22	0.931

The use of four-point blocks is useful when small areas are to be treated which do not permit the placing of a nine block. A group

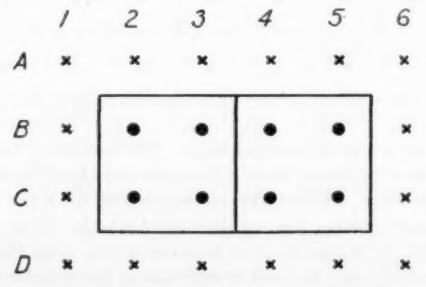

FIG. 4 DIVISION OF A NET INTO GROUPS OF FOUR POINTS EACH

of this nature is shown in Fig. 4. Assuming the boundary values to be given and arbitrary values assigned to interior points, improvement is made as follows

$$\psi'_{B2} = \frac{1}{24}\Big[7(\psi_{A2} + \psi_{B1}) + 2(\psi_{A3} + \psi_{C1} + \psi_{B4} + \psi_{D2}) + \psi_{D3} + \psi_{C4}\Big]$$

$$\psi'_{C3} = \frac{1}{4}(\psi'_{B2} + \psi_{B4} + \psi_{D4} + \psi_{D2})$$

$$\psi'_{B3} = \frac{1}{4}(\psi'_{B2} + \psi_{A3} + \psi_{B4} + \psi'_{C3})$$

$$\psi'_{C2} = \frac{1}{4}(\psi_{C1} + \psi'_{B2} + \psi'_{C3} + \psi_{D2})$$

The points are to be improved in the foregoing order, using improved values as soon as they are available in the succeeding formulas. The rate of convergence resulting from this procedure is greater than that for the Liebmann but less than that for the nine block. Table 3 gives values of λ_1.

TABLE 3

p	λ_1
5	0.347–0.444
9	0.753–0.779
13	0.878–0.886

Further reduction of the λ_1 values may be secured by the use of still larger blocks of points, but the complication of the formulas increases rapidly and the gain in reduction per traverse is more than offset by the labor involved. Experience of the authors indicates that the most satisfactory method for handling an area with any considerable number of interior points consists in fitting into it as many blocks of nine points as possible, then as many blocks of four as possible, and finally treating the remaining points by the Liebmann formula.

THE DIFFERENCE FUNCTION

A further saving in labor is achieved by carrying out operations on what will be designated the difference function, which represents the change in ψ with one traverse. Suppose one operation is carried out on a net such as Fig. 1, obtaining the first set of improved values for the interior points. Then let the initial net values be subtracted at each point from this set of improved values. These differences may now be treated with the same improvement formulas as the original set of values. Certain advantages are inherent in this treatment. In the first place, the number of significant figures is reduced in general, so that the labor of calculation is also reduced. The boundary values of the difference function vanish and hence give many zero terms in the improvement formulas. Finally, the successive traverses over this net soon result in the reduction of the value at each point by a factor λ_1 directly, so that succeeding values form a geometric series which approaches zero and which permits of convenient extrapolation. It will be seen that successive values, obtained on the difference net, represent amounts which must be added to the original net values in order to obtain the actual values of ψ. This represents an additional step which must be performed with this procedure, but the over-all labor is sufficiently reduced so that this is not objectionable. In practice it is logical to add all but the first value on the difference net to the first improved value of the original net. Thus, if $\psi, \psi', \psi'', \psi''', \psi^{(iv)}$ are the original and successive improved values at a given point on the original net and, if δ, δ', δ'', and δ''' are successive improved values on the difference net

$$\delta = \psi' - \psi$$

and, for example,

$$\psi^{(iv)} = \psi' + (\delta' + \delta'' + \delta''')$$

Since the type of series represented by successive values on the difference net is similar to Equation [2], it becomes a simple matter to extrapolate to a final value after all except the highest eigenfunction have disappeared. Suppose that after the difference net has been traversed k times, the values at each point become roughly a constant fraction of their immediate predecessors with each improvement, that is,

$$\delta^{(k+1)} = \lambda_1 \delta^{(k)}$$

Then successive values of the difference function may be represented as $\delta^{(k)}$, $\lambda_1\delta^{(k)}$, $\lambda_1^2\delta^{(k)}$, $\lambda_1^3\delta^{(k)}$, ... etc., and the sum which is to be added to the first improved value ψ' to get the final solution is

$$\begin{aligned}&\delta' + \delta'' + \ldots + \delta^{(k-1)} + \delta^{(k)} + \lambda_1\delta^{(k)} + \lambda_1^2\delta^{(k)} + \lambda_1^3\delta^{(k)} + \ldots . \\ &= \delta' + \delta'' + \ldots + \delta^{(k-1)} + \delta^{(k)}(1 + \lambda_1 + \lambda_1^2 + \lambda_1^3 + \lambda_1^4 + \ldots) \\ &= \delta' + \delta'' + \ldots + \delta^{(k-1)} + \delta^{(k)}/(1 - \lambda_1)\end{aligned}$$

Thus if a series of values at a point on the difference net reduces as follows: 100, 90, 81, 72.9, etc., it is seen that λ_1 is 0.9 and the series is

$$100\ (1 + 0.9 + \overline{0.9^2} + \overline{0.9^3} + \overline{0.9^4} + \ldots)$$

for which the sum is

$$\frac{100}{(1 - 0.9)} = \frac{100}{0.1} = 1000$$

By considering the last term of the series one may write the sum as

$$100 + 90 + 81 + \frac{72.9}{(1 - 0.9)}$$

which of course also turns out to be 1000.

By determining in this way the sum of the series of values which results from repeated traverses over the difference net, and adding this sum to the first improved value as described, an extrapolated value is obtained which will be very close to the true solution of the Laplace difference equation in the region under consideration. Then, for all but the smallest nets, the following procedure applies:

1 Determine the boundary values at intersections of the net with the boundary.

2 Assign arbitrary values to interior points of a coarse net, say, of ten to fifteen points, carrying an arbitrary significant figure beyond that given by the boundary data.

3 Apply the Liebmann procedure to approximate convergence.

4 Transfer the values obtained to a net of one half the net interval (four times as many interior points) carrying another arbitrary significant figure (two in all).

5 Divide the area into as many nine-point and four-point blocks as possible.

6 Improve the values once to obtain ψ'.

7 Subtract to obtain the difference function δ.

8 Improve the difference net *in the same order* until fairly smooth convergence is indicated.

9 Determine the limit of the series of improved values at each point.

10 Extrapolate to obtain the final ψ-value.

11 Improve this value once as a check on convergence.

12 If necessary calculate new differences and repeat the extrapolation, or transfer the values to a finer net and repeat Items 4 to 11, depending on the accuracy desired.

Application

As an illustration of the application of this method to an actual photoelastic problem, a compression piece has been chosen with symmetrical notches, Fig. 5. This is a shape which is quite familiar to most workers in the field of photoelasticity since it has been used frequently in the literature to illustrate both theoretical and practical points. In connection with this model, certain assumptions have been made. The stress in the shanks of the model at points removed from the notches is assumed to be substantially uniform and equal to P/A. This enables a consideration of the central section of the model, omitting any discussion of the points at which the load is applied. The sections through

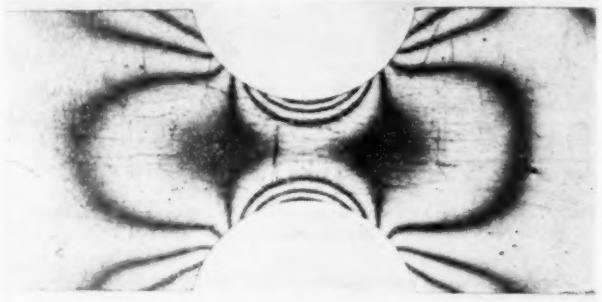

Fig. 5 Light-Field Fringe Photograph of Notched Compression Piece

(This shows the section of the model which was actually considered. The remaining portions of the shank were subjected to stress which was substantially uniform across the cross section. This permitted the use of the sections lying at the ends of the figure as artificial boundaries. The model was cut from clear bakelite, 1/4 in. thick, and was loaded in compression. Actual stresses in pounds per square inch may be taken as 342 times the fringe order. In this paper no actual stresses were computed, all data being given in equivalent fringe order.)

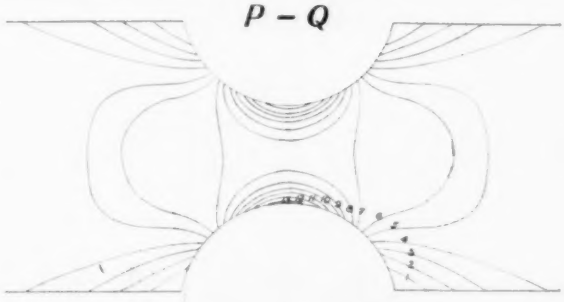

Fig. 6 Isochromatic Lines

(Obtained from Fig. 5 and a similar dark-field photograph. Center lines of the dark fringes were traced from each and superposed.)

the shank at the edges of Fig. 5 are taken as artificial boundaries along which the stress is constant and at which it may be taken as equal to the value at the boundary. The sum of the principal stresses is then known across this section. These lines constitute a part of the boundary of the model as it will be discussed. It further appears that there are two axes of symmetry in this shape, so the labor of solution will be reduced by a factor of about four by using these as outlined. In order to arrive at a more nearly representative solution, the fringe positions were averaged for the four quadrants of the model, the resulting average fringes being shown in Fig. 6. It may be of interest to note that these fringes were taken in two groups, one with polarizers crossed and the other with parallel polarizers. This gives, in effect, the half-order fringes and thus increases the precision which may be obtained from the data.

In order to evaluate the points at which the net intersected the boundaries of the model a curve was plotted as in Fig. 7. For the

shank of the model this is a plot in Cartesian coordinates and for the notch it is a polar diagram. Points were plotted where the fringes intersect the boundaries and a smooth curve drawn through the points. Values of fringe order were plotted instead of stress in pounds per square inch since the numbers are easier to handle. The boundary values of the net were taken from this curve.

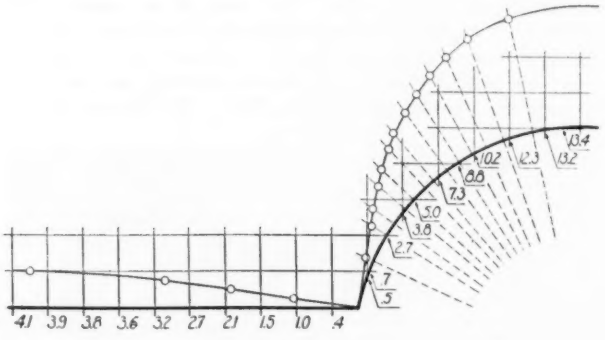

FIG. 7 INTERPOLATION CHART FOR DETERMINING STRESSES AT BOUNDARY POINTS

Three nets were calculated for this model in order to give an idea as to the factors which influence the choice of net fineness. Fig. 8 shows the intermediate net. The other two nets had respectively half the net interval and twice the net interval of this one. Reference will be made to these as the fine and the coarse nets. They were treated as follows: The coarse net was first calculated by the use of the Liebmann procedure, using entirely arbitrary values at the interior points. Final values from this net were transferred to the intermediate net at points which coincided. At other points the initial values for the intermediate net were computed by a diagonal application of the single-point formula and subsequent application of the ordinary single-point formula. Thus the point $D4$ was obtained as

$$\psi_{D4} = \frac{1}{4}(\psi_{C3} + \psi_{E3} + \psi_{E5} + \psi_{C5})$$

where $C3$, $E3$, $E5$, $C5$, etc., were obtained from the coarse net, and the point $D3$ as

$$\psi_{D3} = \frac{1}{4}(\psi_{C3} + \psi_{D2} + \psi_{E3} + \psi_{D4})$$

With each point in Fig. 8 are associated two columns of numbers. The top number in the left column is the original value assigned to the point by the coarse net. Although the boundary values were taken as significant to only two figures, three figures were carried in the interior of the coarse net and four in the other two nets. This was done to insure that the final result should contain no rounding-off errors and also to permit a closer observation of the improvement process. No decimal points are indicated on the net. In general it seems desirable to carry two more significant figures than the data justify and to discard them when the calculation is complete. Thus the calculation can be terminated when the extrapolation formula indicates that the error is less than 50 in the last place. The second number in the left column is the result of a single traverse over the net, using the appropriate improvement formulas. The order of going over the net is not of great importance, but a specific order must be retained throughout a problem in which the difference net is used. In this case the nine block was improved first; then points $A2$, $A3$, $A4$, $D5$, $D6$; the four block in the order $C5$, $B6$, $B5$, $C6$; then $A5$, $A6$, $C7$, $B7$, $A7$, $B8$, $A8$, $B9$, and $A9$. Points $D6$, $C7$, $B8$, and $B9$ were so placed that the boundary point formula was necessary. These were therefore treated as discussed under that heading. Thus point $D6$ was improved by the formula

$$\psi'_{D6} = 0.1448\psi_{D5} + 0.1188\psi_{C6} + 1243$$

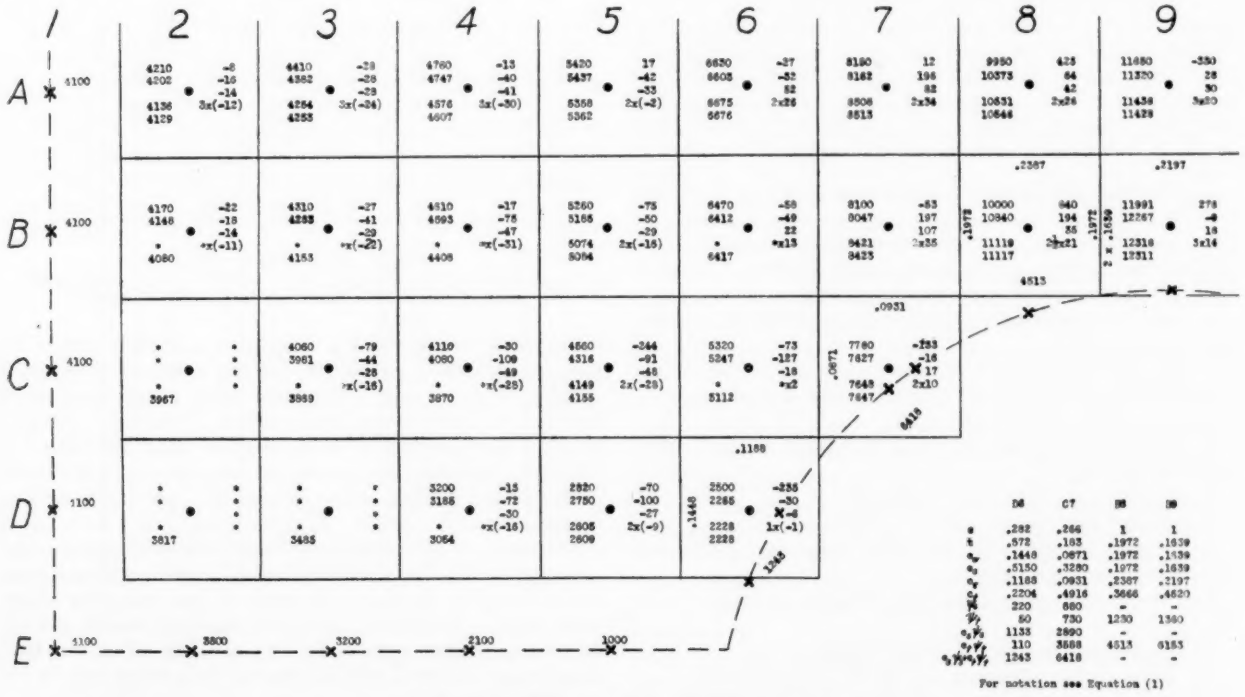

FIG. 8 SOLUTION OF THE INTERMEDIATE NET

(The table gives data for the calculation of the coefficients of the points near the boundary. These are written in the corresponding squares adjacent to the neighbors to which they apply. Values in the net marked * are not needed in subsequent calculations and hence were not computed.)

The first number in the right-hand column is the difference of the second and the first in the left column. This establishes the difference function with which to proceed in further iteration of the improvement formulas. The difference function was improved three times, giving the succeeding values in the right column. It will be observed that positive and negative areas tend to develop, each finally decreasing. If the iteration were prolonged sufficiently, the values would become one-signed and smoothly distributed. The authors did not wait for this, however, but proceeded to extrapolate after the third traverse over the difference net, since at this point the difference function had approximately a stationary node. Thus it evidently contained little of the first (nodeless) eigenfunction of the process but resembled more one of the other eigenfunctions. For this reason the error is decreasing more rapidly than would ordinarily be expected. The decrease seems to be by a factor of about $^2/_3$, so a multiplying factor $1/(1 - {}^2/_3) = 3$ has been used in the center of each pillow. Near the node where the decrease is more rapid smaller factors have been used. From observation of a converging series a reasonable guess is thus being attempted as to how far it is going. The choice of multiplying factors is influenced by a knowledge of the λ_1-value for an equivalent square area, by judgment acquired through experience, by the observed rate of decrease of particular points, etc. The exact amount by which each point is extrapolated is not so very important so long as the overall treatment is about correct. This is due to the rapidity with which a random error is ironed out by the subsequent application of the improvement formula.

The third value in the left column at each point is now obtained by adding the second, third, and fourth entries in the right-hand column to the second value on the left. Consider the point *B*5. The value 5260 was assigned from the previous coarse net, but in so far as treatment is concerned, it might have been entirely arbitrary. The value 5185 resulted from a single traverse over the net in the order indicated previously. The difference of 5185 and 5260 is —75, the top right value. Subsequently —50, —29, and —16 were obtained by traversing the difference net. The final multiplier for the last value was taken to be 2 as indicated by the considerations above. The sum of —50, —29, and 2 × (—16) and 5185 then gave 5074, the third value in the left column. This is the result of the extrapolation procedure. A final traverse is now made over the net, using extrapolated values, the result being the number 5084 at *B*5. This is considered to be the solution of the problem. Now drop the two significant figures which were added earlier and place the decimal point, giving the equivalent fringe value as 5.1 at this particular point. The degree to which it really represents a solution may be determined by the use of a finer net. Fig. 9 shows the arrangement of blocks in the fine net. Here the size permitted the use of six complete nine blocks, and three more which were split along an axis of symmetry.

The results of the fine net were obtained by a process identical with that employed on the intermediate net, except that after the first extrapolation was made, a second was also performed, in order to leave no doubt as to the correctness of the result. Table 4 shows the values obtained at various points from each of the three nets.

TABLE 4

Point	Coarse	Intermediate	Fine
*A*3	4.4	4.3	4.2
*A*5	5.4	5.3	5.3
*A*7	8.2	8.5	8.6
*A*9	11.7	11.4	11.3
*C*3	4.1	3.9	3.8
*C*5	4.6	4.1	4.1
*C*7	7.8	7.7	7.7

It will be observed that there is no significant change in going from the intermediate to the fine net. The coarse net, however, was somewhat farther from the final values than is desirable in this problem.

The results of the calculations were plotted as contours of constant $(S_1 + S_2)$, forming what are generally known as isopachic lines. These are shown in Fig. 10. When these are combined with the isochromatic lines, the several principal stresses can be separated. These separate values are given in Fig. 11. Thus the problem is completed.

Conclusions

Commenting upon what has been presented; with regard to

the photoelastic problem which was used as an illustration, it may be said that the result represents as nearly the correct values as it is possible to obtain with any method depending on the fringe pattern. No possible significant error can exist in the numerical treatment of the data. In the present instance the authors went to a great deal more trouble than was necessary in solving the problem. The intermediate-net solution was entirely adequate in so far as engineering accuracy was concerned.

As to the time consumed in this method, it will be of interest that the solution by the intermediate net, after the boundary values had been obtained, required approximately two hours. This is based upon two persons using a computing machine. The fine-net solution required about seven hours. The time necessary in working over the original coarse net was very short. It is estimated that the total amount of work included in this problem could be accomplished by one experienced person in a day. This represents a marked saving of time and energy over other methods which have been employed for this type of work.

It is evident that the method is a general one which may be applied with profit to many other fields, such as steady-state heat conduction, electric fields, membrane shapes, and perhaps certain problems in hydrodynamics and gravitation.

Creep, Elastic Hysteresis, and Damping in Bakelite Under Torsion

By HERBERT LEADERMAN,[1] CAMBRIDGE, MASS.

The creep in torsion of various forms of bakelite under constant load and the creep recovery on removal of load is found to follow closely the superposition principle or "memory law" of Boltzmann, if the previous maximum strain in a test is not exceeded. If the previous maximum strain is exceeded, an additional plastic flow takes place which is not, at any rate immediately, recoverable.

A function of the elapsed time called the "equivalent time" is introduced in order to analyze the creep and creep recovery when the loading history is complex.

A method is developed for calculating the stress-strain loop due to creep for step-by-step cyclic loading. Results of cyclic-loading tests reveal the presence of a true elastic-hysteresis loop in addition to the loop due to creep.

The specific damping capacity in torsion at a given stress, calculated from the measured creep and elastic-hysteresis loop, is shown to agree fairly well with the damping measured directly.

The Inelastic Phenomena

THE PROBLEM of the dissipation of mechanical energy under alternating stress, known as damping capacity, has in the past received much attention both in America and in Europe. It was originally hoped that damping capacity in metals might be an important factor in limiting the amplitude of resonant vibrations. Unfortunately, damping in metals appears to be too small to be of much use in this respect. In synthetic materials however damping can be large, and can therefore be more easily measured and studied. The following investigation was undertaken to elucidate the nature of damping and related phenomena in various commercial forms of bakelite. The conclusions drawn from this investigation are probably true for other organic materials as well.

It was originally thought that damping capacity as manifested by the decay of torsional oscillations of a pendulum was of the nature of a solid friction, analogous to fluid friction. This concept leads to the conclusion that the logarithmic decrement (the natural logarithm of the ratio of successive oscillations) is independent of stress but proportional to frequency. In practice, over the usual range of frequencies, this quantity is found to be a function of stress but independent of frequency. On the other hand, the assumption that damping is due to a departure from perfect elasticity is in agreement with experimental evidence. The study of damping is therefore the study of the small imperfections of elasticity within the elastic range.

Damping and Elastic Hysteresis. Damping is usually measured by a nondimensional quantity, the specific damping capacity ψ, which is the ratio of the energy dissipated in one oscillation to the strain energy present at the maximum amplitude of the oscillation

$$\psi = \Delta W/W \quad [1]$$

This is just twice the logarithmic decrement δ when this is small. We can thus measure the damping capacity of a specimen by the decay of torsional oscillations of a system in which the specimen forms the elastic member.

Careful measurements by Rowett (1)[2] of the stress-strain relationships of steel tubes under reversed torsion over a given stress range showed that this relationship was not exactly a straight line but was in fact a narrow closed loop. These loops of course correspond to a loss of energy on traversing a cycle. The specific damping capacity calculated from the static tests agreed closely with values obtained by measuring the decrement of free oscillations from the dynamic tests. The stress-strain relationship was a narrow closed loop, of the same shape and size, no matter how speedily or how slowly the stress-strain test was made. Such a stress-strain loop is usually referred to as an elastic-hysteresis loop. Since elastic hysteresis is a phenomenon independent of time, this can be a cause of damping capacity independent of frequency.

Primary and Secondary Creep. In amorphous materials such as glass, and also to a small extent in metals, the strain under constant stress varies with time. This phenomenon is known as "creep." In hard metals and in glass at room temperature the creep varies approximately as the logarithm of the time since the application of the load (2, 3). At higher temperatures there is a superimposed plastic flow in which the creep is proportional to time but not necessarily to stress. Under these conditions the deflection x varies with the time of application of load t according to the equation

$$x = b + a \log_{10} t + ct \quad [2]$$

where the term ct represents the plastic flow; this is of appreciable magnitude in metals, only at elevated temperatures. The creep rate

$$dx/dt = (a'/t) + c \quad [3]$$

at first decreases with time and then becomes approximately constant (4). Kanter (5) has referred to the first stage of creep where the logarithmic component is predominant as the "primary stage," and to the stage where the plastic flow is predominant as the "secondary stage." It is suggested as an extension of these definitions that the logarithmic component be called "primary creep" and the plastic-flow component "secondary creep."

The physical distinction between the two components is roughly that secondary creep is analogous to fluid flow, in that it represents a permanent distortion which is not recovered on removal of load. On the other hand, the deflection due to primary creep is gradually recovered after removal of load, as a negative creep or creep recovery takes place. The creep of bakelite at low stresses is very largely primary creep.

The Memory Law or Superposition Principle of Primary Creep. The law of primary creep and creep recovery was first enunciated

by Boltzmann (6), and has been restated in other forms by Bennewitz (3) and Becker (7). The basic principle is that the primary creep of a specimen of material is a function not only of the last load applied, but also of the previous loading history. If for example a cylindrical specimen of bakelite is twisted first in one sense and then for a short time in the reverse sense, after the load is removed it recovers at first in the opposite direction to the latter twist. This recovery slows down, ceases, and then reverses. Fig. 1 shows the nature of creep recovery after such a

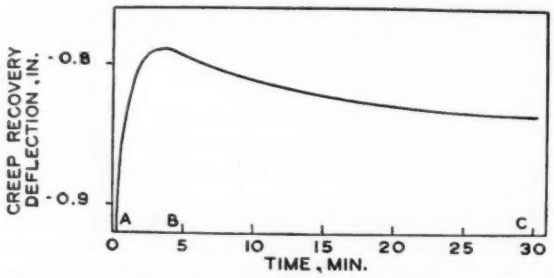

FIG. 1 CREEP RECOVERY AFTER TORSION LOADING IN OPPOSITE DIRECTIONS

(Angular twist in radians equals deflection divided by the optical lever arm of 148.4 in.)

loading history. This recovery can be explained by assuming that the specimen possesses a "memory," and that from A to B, Fig. 1, the memory of the more recent briefer action exceeded the memory of the earlier action of longer duration; from B to C the reverse is the case. The general theory of Boltzmann assumes that the rate of primary creep is a function of the entire loading history, and that the creep rate due to each augmentation of load is proportional to the increase in load and to a function of the time elapsed since the application of the load; the effect of each loading action is assumed to continue indefinitely. Removal of load is regarded as being equivalent to the addition of a negative load. If for example a load W be applied at time t_0, and if t be the current time, the creep rate at time t will be given by

$$dx/dt = Wa\varphi(t - t_0) \quad [4]$$

If the load be then removed at time t_1, the subsequent creep rate at time t will be given by

$$dx/dt = Wa\varphi(t - t_0) - Wa\varphi(t - t_1) \quad [5]$$

The assumption of logarithmic creep due to a single load is equivalent to assuming for the function $\varphi(t)$ a value $1/t$. Hence the creep rate for a load W applied at time t_0 and removed at time t_1 becomes

$$\frac{dx}{dt} = Wa\left[\frac{1}{t - t_0} - \frac{1}{t - t_1}\right] \quad [6]$$

This is negative, indicating that a creep recovery is taking place. The deflection x therefore varies with time t according to the equation

$$x = Wa \log\left(\frac{t - t_0}{t - t_1}\right) \quad [7]$$

If the load be reapplied at t_2, the subsequent deflection will be given by

$$x = Wb + Wa \log \frac{(t - t_0)(t - t_2)}{(t - t_1)} \quad [8]$$

where Wb represents the elastic deflection. If it be assumed that the creep rate due to a given load is proportional to that load, then in general, if the load be applied at times t' in increments W, he deflection at a subsequent time t will be given by

$$x = b\Sigma W + a\Sigma W \log(t - t') \quad [9]$$

Primary Creep and Damping. The creep due to a sinusoidal applied load will now be considered. Under certain assumptions (6, 7, 8) it can be shown that the deflection, due to the action of the "memory," is also sinusoidal but lags behind the deflection by a small angle ϕ; in other words the dynamic stress-strain curve due to the action of creep is a narrow ellipse, and hence primary creep obeying the memory law can be a cause of damping. The mathematical theory indicates that the specific damping capacity due to primary creep should be independent of frequency over a wide range of frequencies (7). The specific damping capacity due to creep is then

$$\psi = 4\pi\Phi = \frac{\pi^2 a}{Mb} = 4.28\,\frac{a}{b} \quad [10]$$

where $M = \log_e 10$, b is the elastic deflection per unit load, and a is the slope of the plot of the creep curve per unit load against logarithm (to base 10) of the equivalent time (in the absence of secondary creep). This formula has been used (8) to show that the directly measured damping for glass agrees closely with that computed from the creep measurements.

CREEP AND ELASTIC HYSTERESIS

Using cylindrical bakelite specimens in torsion, the author found that the measured damping was much greater than that computed from the creep using Equation [10]. It was considered that the discrepancy might be due to the presence, in addition to primary creep, of a true elastic hysteresis, of a statical nature independent of time. It was of course impossible to measure the area of the elastic-hysteresis loop directly by the method of Rowett, since the creep was of such magnitude as to interfere with the true elastic hysteresis, if the latter were present. Accordingly, static tests were made in which the load was applied in equal steps up to the maximum load; the load was then removed in steps of equal magnitude. In this manner stress cycles were traced. Increase or decrease of load took place in equal intervals of time; the reading corresponding to the twist of the specimen was made just before the load change. In this way stress-strain loops were obtained. It was now necessary to determine whether the width of loop at any load level could be accounted for entirely by creep. Accordingly the Boltzmann memory law was used to calculate the deflections due to creep for this particular loading pattern, and a separate creep test was made to determine the value of the creep constant a.

It was found, after applying the corrections due to creep deflection to each observation, that a finite width of loop remained, indicating that there was a true elastic-hysteresis loop. Repeating the step-by-step cyclic-loading test with different time intervals gave for the same stress range nearly the same value of hysteresis-loop area. The combined contributions to damping of primary creep (calculated from a creep test) and of elastic hysteresis (calculated from the deduced elastic-hysteresis loop) agreed reasonably well with the value obtained for the same stress range from the decrement of free oscillations of the specimen. It is to be concluded, for the four commercial forms of bakelite tested, that there exists a true elastic hysteresis as well as a primary creep, and that the damping is due to the action of both these inelastic phenomena.

THEORETICAL AND EXPERIMENTAL METHODS

The conclusion just stated was reached after a four-fold attack on the problem. First, methods were devised to test the memory law. Secondly, these methods were applied to four specimens of bakelite in torsion. Thirdly, the Boltzmann memory law was used to calculate the deflections due to creep in the step-by-step

cyclic-loading tests. Finally, cyclic-loading and decrement tests were made. From the former the damping due to creep and hysteresis was calculated, and from the latter the damping was obtained directly.

Materials Used. A complete set of tests was made on each of four types of bakelite material:

(*a*) Phenol-formaldehyde resin, white, transparent, and unfilled, as used for photoelasticity tests.

(*b*) Bakelite commercial molding material with wood-flour filler.

(*c*) Bakelite X 199 shock-resisting material. The filler consisted of fabric snippings impregnated with phenol-formaldehyde resin and molded. These three materials can be considered to have an isotropic structure.

(*d*) Bakelite cord material. The reinforcement consisted of closely packed cotton cords running parallel to the axis of the specimen.

Solid cylindrical specimens were tested in torsion, with the load applied by means of weights hung from the ends of a lever arm. For the creep and cyclic-loading tests, light, reflected onto a fixed vertical scale from a front-silvered mirror attached to the bar, was used to obtain readings of the torsional deflection. For the damping tests a high light reflected from a ball bearing was photographed on a moving strip of cinematograph film. The load was released by burning through a cotton thread, the lever arm acting as the inertia bar.

Tests of the Memory Law

As was previously shown, the deflection at a time t according to the memory law is equal to the elastic deflection together with a deflection proportional to the logarithm of a function of time dependent on the previous loading history; for example, if a load W be applied at time t_0, removed at time t_1, and reapplied at time t_2, the time function for the subsequent creep will be, from Equation [8]

$$(t - t_0)(t - t_2)/(t - t_1) \quad \ldots\ldots\ldots\ldots\ldots\ldots [11]$$

Let such a time function be called the "equivalent time." The concept of equivalent time will be shown to be a powerful tool in separating primary creep, secondary creep, and elastic deflection for any complex loading history.

For each material the following three tests were made.

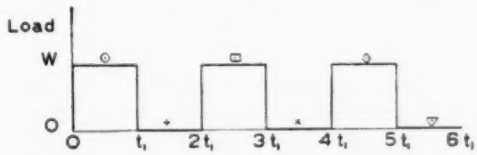

Fig. 2 Loading Diagram for Test A, Torsion Repeated-Loading Test

(The symbols on the diagram correspond with those in Fig. 5.)

Test A, Repeated Loading. Fig. 2 represents the loading diagram for this test. A given load W was applied for 10 min and the deflection read at intervals during this period. The load was then removed and the deflection read during a recovery period extending over an equal interval of time; the load was then reapplied. The unloading and reloading process was continued for a total of 60 min. It follows from the Boltzmann law that the equivalent times for the creep periods are

$$t, \quad \frac{t(t-2t_1)}{t-t_1}, \quad \frac{t(t-2t_1)(t-4t_1)}{(t-t_1)(t-3t_1)} \quad \ldots\ldots\ldots [12]$$

and for the recovery periods

$$\frac{t}{(t-t_1)}, \quad \frac{t(t-2t_1)}{(t-t_1)(t-3t_1)}, \quad \frac{t(t-2t_1)(t-4t_1)}{(t-t_1)(t-3t_1)(t-5t_1)} \ldots [13]$$

respectively, where t is the time from the beginning of the experiment, and t_1 is in this case equal to 10 min. In the absence of plastic flow, the deflections observed in the creep periods when plotted against the logarithm of the equivalent time should lie along one straight line of slope Wa, and the deflections in the recovery periods should lie along a parallel straight line.

Test B, Primary Creep and Stress. The purpose of this test was to prove that the primary creep was proportional to stress. Test A was carried out to say an elapsed time of $4t_1$ min, and then repeated after a while with half the load. See Fig. 3 (*a*) and (*b*). The slope of the creep-recovery line in the second test should be half of that in the first test.

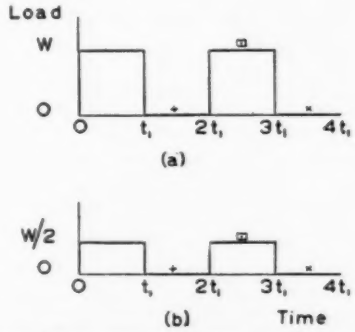

Fig. 3 Loading Diagrams for Test B, Primary Creep and Stress in Torsion

(The symbols correspond with those in Fig. 6.)

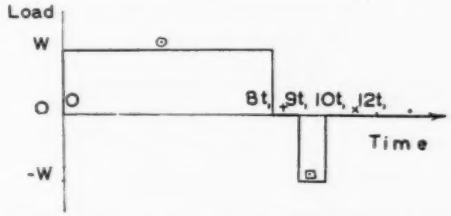

Fig. 4 Loading Diagram for Test C, Memory-Law Test, Torsion

(The symbols correspond with those in Fig. 7.)

Test C, Memory-Law Test. Fig. 4 represents the loading diagram for this test. The load was applied from time $t = 0$ to $t = 8t_1$, and then removed. The load was applied in the reverse sense from $t = 9t_1$ to $t = 10t_1$ and then finally removed. This form of test was so chosen that the memory law could be tested in the absence of any possible complications from plastic flow.

The equivalent time for the creep recovery from $t = 10t_1$ onward is then

$$t(t - 10t_1)/(t - 8t_1)(t - 9t_1) \quad \ldots\ldots\ldots\ldots [14]$$

This has a maximum at $t = 12t_1$, i.e., according to the memory law the creep recovery from $t = 10t_1$ to $t = 12t_1$ should be in the direction of the original creep, whereas from $t = 12t_1$ onward it should be in the reverse direction. Furthermore, the creep-recovery deflections from $t = 10t_1$ onward should all lie on a single straight line, when plotted against the appropriate value of the logarithm of the equivalent time.

Results of the Creep Tests

Test A. Fig. 5 shows the result of a test on cord material with the deflections in each of the six stages plotted against the logarithm of the equivalent time. The other specimens gave similar results. It is seen that in the first creep period the plot is not linear, indicating that some kind of plastic flow was taking place in this stage. The first recovery stage, when plotted against the

logarithm of the equivalent time, gives a straight line. The second creep stage gives a line which is straight and parallel to the creep-recovery line up to the termination of the first creep stage; for the rest of this period there is a further plastic flow. The second recovery stage gives a straight line parallel to but displaced from the first by an amount equal to this plastic flow. It is seen that the Boltzmann memory law gives correctly the nature of the creep recovery and also of the creep if the previous maximum strain is not exceeded. When stress-strain loops are traced therefore, it is safe to say that, within the stress range considered, after the first loop no plastic flow occurs and the creep and creep recovery are given completely by the Boltzmann law.

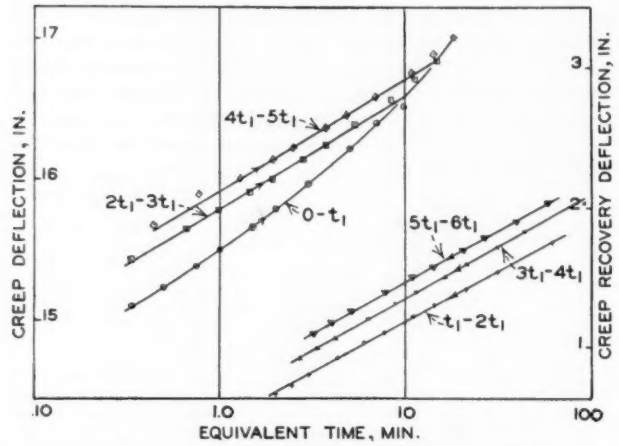

FIG. 5 CREEP AND CREEP RECOVERY, TEST A, CORD MATERIAL

(The left-hand scale refers to scale deflections under a torque load of 15 lb-in., and the right-hand scale to the recovery deflections. The angular twist in radians is obtained by dividing the deflection by the optical lever arm, 148.4 in. The symbols used for each creep and recovery stage correspond with those in Fig. 2. Time t_1 = 10 min.)

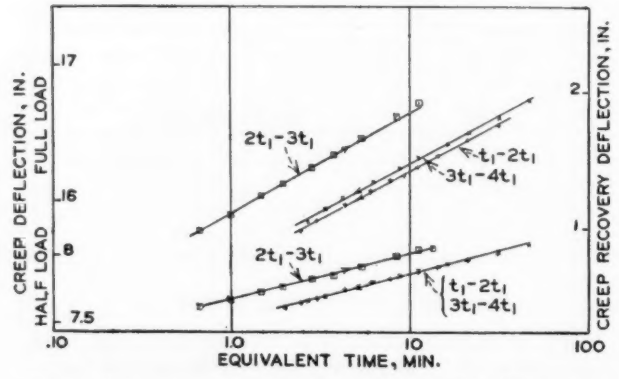

FIG. 6 CREEP AND CREEP RECOVERY, TEST B, CORD MATERIAL

(Tests at full load (15 lb-in.) and half load. In neither case is the first creep stage recorded. The symbols correspond with those in Fig. 3. Time t_1 = 10 min.)

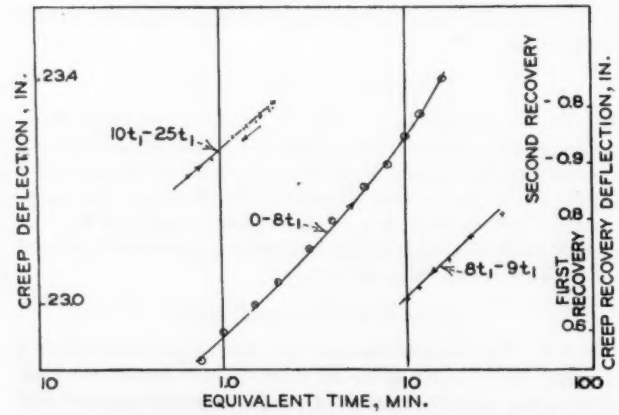

FIG. 7 CREEP AND CREEP RECOVERY, TEST C, BAKELITE RESIN

(The second creep stage is not recorded. The second recovery stage in this test is plotted in Fig. 1 against a linear time base. The symbols correspond with those in Fig. 4. Time t_1 = 2 min.)

Test B. Fig. 6 shows the first and second creep-recovery stages, and the second creep stage for cord material, with 10-min creep and recovery intervals as before. The lower set of lines refers to creep and recovery using one half the load used to obtain the upper set. It is seen that the slope of the upper lines is almost exactly twice that of the lower set, indicating that primary creep is proportional to the applied load for the cylindrical specimen. Therefore it follows the primary creep is proportional to stress, and hence the stress distribution across the cross section of the cylindrical specimen remains linear.

Test C. Fig. 7 shows the result of a test on transparent unfilled resin. The unit of time t_1 in this test was equal to 2 min. The creep recovery during the final recovery stage lies on a straight line when plotted against the logarithm of the equivalent time, and reverses in direction at $12t_1$ or 24 min, as predicted by the Boltzmann law. The creep recovery from $8t_1$ or 16 min to $9t_1$ or 18 min is also shown; this is a parallel straight line, displaced by an amount corresponding to the plastic flow in the intervening creep stage. By comparison the creep recovery from $10t_1$ or 20 min onward is plotted directly against time in Fig. 1.

It is to be concluded that for short-period tests at low stresses the primary creep and creep recovery obey the Boltzmann memory law, and that plastic flow is not a disturbing factor.

STRESS-STRAIN LOOP DUE TO CREEP

Let it be assumed that a cylindrical specimen is loaded in equal steps in reversed torsion, and that one quarter of the maximum load $\pm 4W$ is applied or removed in each step. Each loading increment or decrease takes place in equal intervals of time t_1, and the torsional deflection is observed just before the load change takes place. Due to the action of primary creep, stress-strain loops will be obtained. By means of the Boltzmann law it is possible to calculate the deflection due to creep for each observation. From the slope of the creep lines obtained from such a test as test A, it is then possible to evaluate these deflections. These deflections due to creep subtracted from the observed deflections would reveal whether, in addition to primary creep, elastic hysteresis were present and, if this were so, the area of the elastic-hysteresis loop.

In calculating the stress-strain loop due to creep, a theoretical difficulty arises. In the absence of plastic flow, the creep deflection due to a single load W is given by

$$x = W(b + a \log t) \quad \ldots\ldots\ldots\ldots\ldots\ldots [15]$$

This equation appears to be true for very small values of t, and consequently a value of "immediate elastic deflection" cannot be defined. If however Wb (the deflection at unit time) be called the "time-independent" part of the deflection and $Wa \log t$ the "time-dependent" part, then it is possible to calculate the time-dependent part for any given loading history. If this happens to be negative, it means that the deflection with the given loading history is less than that which would be obtained (of course in the absence of elastic hysteresis and plastic flow) if the same load were applied for unit time. The unit of time in all this work was one minute, though of course the results would not be affected if one second or one hour were used as the time unit.

In the experimental work, a radius arm of 7.5 in. was used; the maximum load of 2 lb was applied in four equal steps of $\frac{1}{2}$ lb

on a specimen $^5/_{16}$ in. in diameter corresponding to a maximum stress range of ±2520 psi. The effective length of the specimen was 2 in. The time intervals between load changes were in different tests $^1/_2$ min, 1 min, and 2 min. Two complete cycles were traced in each test, but the observations of the second cycle only were considered. In this way the effects of plastic flow were probably eliminated.

The procedure was to calculate the creep due to the previous loading history in terms of the current time t, reckoned from the beginning of the experiment, and then to substitute for t. The load W was applied at $t = 0$. The subsequent deflection is given by Equation [15]. Hence the deflection at t_1 is $W(b + a \log t_1)$. At this instant the load was augmented to $2W$. The subsequent deflection is given by

$$W(b + a \log t) + W[b + a \log(t - t_1)] = 2Wb + Wa \log t(t - t_1) \quad [16]$$

Hence deflection at time $2t_1$ is given by

$$2W(b + a \log t_1) + Wa \log 2 \quad [17]$$

At this instant the load was augmented to $3W$, and the subsequent deflection is

$$3Wb + Wa \log t(t - t_1)(t - 2t_1) \quad [18]$$

Deflection at $3t_1$ is therefore

$$3W(b + a \log t_1) + Wa \log 3! \quad [19]$$

Similarly, deflection at $4t_1$ is

$$4W(b + a \log t_1) + Wa \log 4! \quad [20]$$

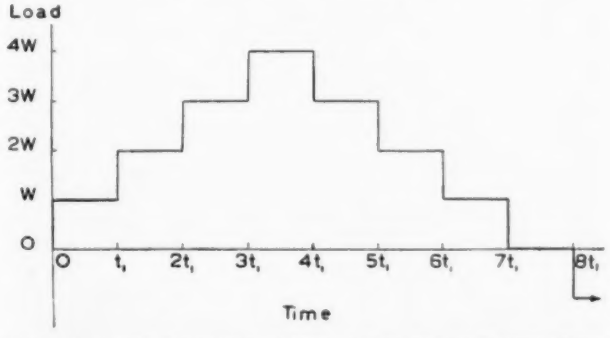

FIG. 8 LOADING DIAGRAM FOR STEP-BY-STEP CYCLIC-LOADING TESTS

Fig. 8 represents part of the loading diagram for the step-by-step cyclic-loading tests. From the diagram it is seen that the deflection from $5t_1$ to $6t_1$ is

$$2Wb + Wa \log \frac{t(t - t_1)(t - 2t_1)(t - 3t_1)}{(t - 4t_1)(t - 5t_1)} \quad [21]$$

Hence the deflection at $6t_1$ is

$$2W(b + a \log t_1) + Wa \log \frac{6!}{2!2!} \quad [22]$$

Similarly, the deflection at $8t_1$ is

$$Wa \log \frac{8!}{4!4!} \quad [23]$$

It is seen that the deflection at any given load station nW consists of a part $nW(b + a \log t_1)$ together with a part $Wa \log F$ where F is a factorial function dependent on the load history. It is seen further that a stress-strain loop due to the action of primary creep has appeared and that the width of this loop is independent of the loading interval; the effect of altering the time interval t_1 is to shear over the loop by an amount proportional to $\log t_1$. It is necessary therefore to consider only the progress of the factorial function F with loading history. At $t = 4t_1, 12t_1, 20t_1, \ldots\ldots$, a discontinuity of the loading process occurs, and hence F changes in nature. At $8t_1, 16t_1, 24t_1, \ldots\ldots$, there is no discontinuity and hence no change in shape in F. From this observation the value of F can be tabulated for the end of each quarter cycle for the first two cycles, as in Table 1.

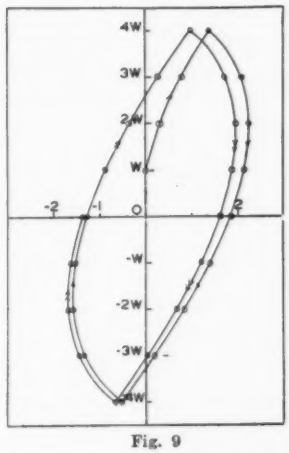

Fig. 9

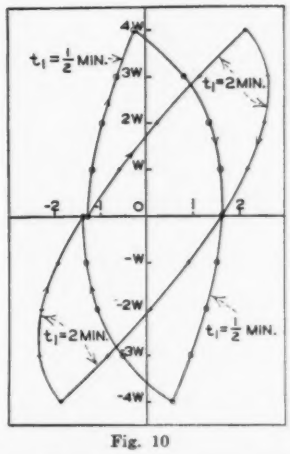

Fig. 10

FIG. 9 TIME-DEPENDENT DEFLECTIONS

(The diagram shows the calculated time-dependent deflections for the first two loading cycles when the loading interval t_1 (Fig. 8) is 1 min. The abscissas, when multiplied by Wa, the slope of the logarithmic-creep plot for load W, give the appropriate creep corrections.)

FIG. 10 TIME-DEPENDENT DEFLECTIONS, SECOND LOADING CYCLE

(The curves give the creep corrections when the loading intervals (Fig. 8) are $^1/_2$ min, and 2 min, respectively.)

TABLE 1 VALUES OF FACTORIAL FUNCTION F

First cycle		Second cycle	
Time	F	Time	F
$4t_1$	$4!$	$20t_1$	$\frac{20!\ 8!\ 8!}{16!\ 16!}$
$8t_1$	$\frac{8!}{4!\ 4!}$	$24t_1$	$\frac{24!\ 12!\ 12!}{20!\ 20!\ 4!\ 4!}$
$12t_1$	$\frac{12!}{8!\ 8!}$	$28t_1$	$\frac{28!\ 16!\ 16!}{24!\ 24!\ 8!\ 8!}$
$16t_1$	$\frac{16!\ 4!\ 4!}{12!\ 12!}$	$32t_1$	$\frac{32!\ 20!\ 20!\ 4!\ 4!}{28!\ 28!\ 12!\ 12!}$

The values of F for intermediate values of t_1 are obtained by using the next succeeding one listed as a model.

Fig. 9 shows the values of $\log F$ for the first two complete cycles. This multiplied by Wa is of course the time-dependent deflection when the loading interval is equal to 1 min. When the load interval is different it is necessary to add an amount $nWa \log t_1$ when the load is nW to obtain the time-dependent deflection. Fig. 10 shows the values of the time-dependent deflections in terms of Wa for the second cycle when $t_1 = ^1/_2$ min and $t_1 = 2$ min, respectively.

For each material, step-by-step cyclic-loading tests of two complete cycles were conducted. For the cord and fabric molding material, three, and for the other two specimens, two tests were made using different values of time interval. For any one material the tests were carried out on the same occasion, with short resting periods between each test; after this a creep test (such as test A) was carried out to determine a, the slope of the logarithmic plot corresponding to $^1/_2$-lb load on the torsion arm. The factor Wa multiplied by the appropriate value of time-dependent deflection recorded in Figs. 9 and 10 gave the actual

values of time-dependent deflections. These deflections when subtracted from the deflections observed in the second cycle of the tests gave the time-independent deflections. These latter may be regarded as the deflections in the absence of primary creep.

Results of Step-by-Step Cyclic-Loading Tests

In all cases after applying the corrections, elastic-hysteresis loops of appreciable magnitude were obtained. The loop areas in different tests on the same specimen showed slight differences; this was attributed to the low over-all accuracy of the tests and to the fact that in practice a small interval of time elapsed between the reading of the deflection and the change of load.

Table 2 gives the observed readings, and these readings corrected for primary creep for the cord material for $t_1 = 1/2$ min, 1 min, and 2 min, respectively; the observed and corrected total strain ranges are also given. In all cases a load of 2 lb on the lever arm corresponds to a torque of 15 lb-in. The observations are in inches of scale with an optical lever arm of 148.4 in. The second cycle only is recorded.

TABLE 2 STRESS-STRAIN LOOPS IN TORSION, SECOND CYCLE

Specimen, cord material, 5/16 in. diam, effective length, 2 in.

$t_1 = 1/2$ min load, lb[a]	Observed loop[b]			Loop corrected for creep[b]		
2		52.81			52.86

Total strain ranges

Time interval, min	Observed loop[b]	Corrected loop[b]
1/2	33.34	33.49
1	33.85	33.54
2	34.35	33.59

[a] Applied on lever arm of 7.5 in.
[b] The observations are in inches of scale. The twist in radians is equal to the scale observation divided by the optical lever arm of 148.4 in.

TABLE 3 MEAN SPECIFIC DAMPING CAPACITY IN TORSION

Material		Computed specific damping capacity, per cent —Time interval, min— 1/2	1	2	Mean
Cord	Creep	22.9	22.9	22.9	
	Hysteresis	15.0	16.1	17.3	
	Total	37.9	39.0	40.2	39.0
Fabric molding	Creep	18.9	18.9	18.9	
	Hysteresis	13.4	15.0	16.0	
	Total	32.3	33.9	34.9	33.7
Wood-flour material	Creep	14.4	14.4	....	
	Hysteresis	18.9	18.9	....	
	Total	33.3	33.3	....	33.3
Bakelite resin	Creep		6.5	6.5	
	Hysteresis		3.5	3.9	
	Total		10.0	10.4	10.2

It is seen that the theory accounts for most of the discrepancy between the observed total strain ranges in the different tests, and this can be regarded as a partial check on the theory. It is also observed that the corrected observations are nearly the same in the three tests. Similar results were obtained in the tests on the other materials.

Computed Specific Damping Capacity. From the slope of the plot of creep against the logarithm of the equivalent time the contribution of primary creep to damping was calculated by means of Equation [10]. From the area of the hysteresis loop (obtained from the step-by-step observations corrected for creep) the contribution of elastic hysteresis to damping at a surface shear stress of ± 2520 psi was calculated by means of Equation [1]. Table 3 gives the computed mean specific damping capacity in torsion for circular cylinders of the four specimens when the surface shear stress is equal to 2520 psi.

Direct Determination of Damping

At the conclusion of the step-by-step cyclic-loading tests, the damping test for each material was carried out. The damping was determined by the decrement of free oscillations, using the loading lever as the inertia bar. Fig. 11 shows typical damping

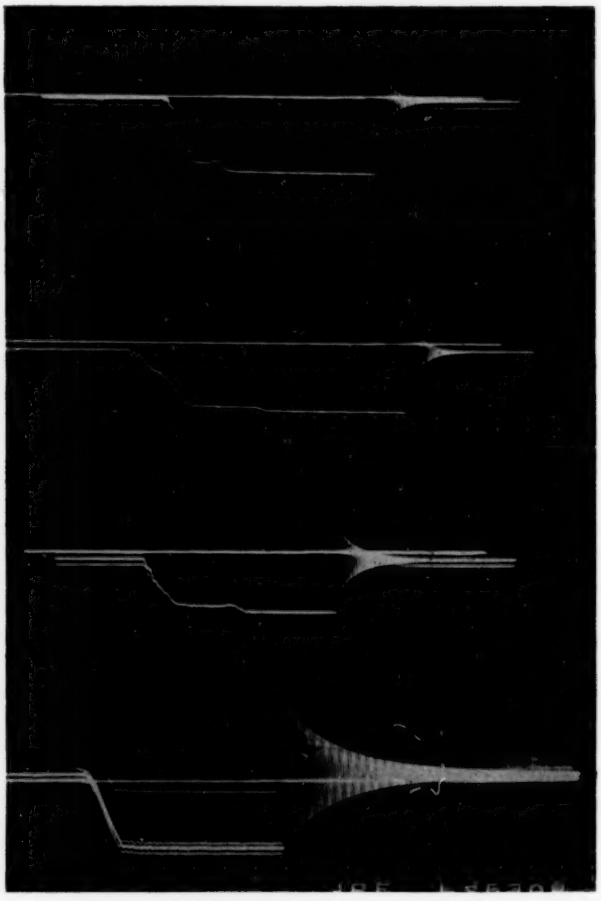

Fig. 11 Decrement of Free Torsional Oscillations
From top to bottom: Cord material
Fabric molding material
Wood-flour material
Bakelite resin, unfilled

records. From the base line of the record the deflection corresponding to the applied load was obtained, and hence the stress corresponding to any given deflection on the film record. The specific damping capacity was computed on the assumption that it was equal to twice the logarithmic decrement at any given stress. Though this assumption is true for small values of

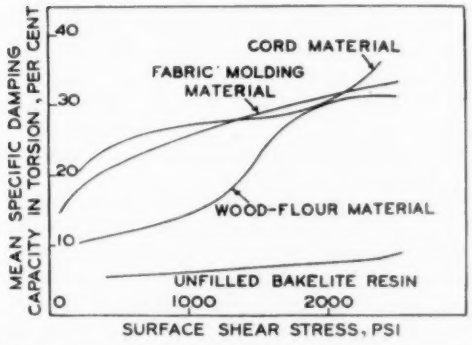

FIG. 12 SPECIFIC DAMPING CAPACITY AND STRESS

damping, it is liable to be in error for the higher values recorded. Fig. 12 shows the relation between the mean specific damping capacity in torsion ψ_m and surface shear stress for the four materials. In all cases the curves were very nearly reproducible. Table 4 shows the values obtained from the curves at a surface shear stress of 2520 psi, compared to the mean values obtained in the static tests.

TABLE 4 MEAN SPECIFIC DAMPING CAPACITY IN TORSION, PER CENT

Material	Cord	Fabric molding	Wood flour	Bakelite resin
Dynamic test	36.6	33.2	31.1	8.9
Static test (mean)	39.0	33.7	33.3	10.2

Though the agreement between the dynamic and the static tests is only fair, it is probable that a more carefully designed apparatus would give better agreement, especially if it were designed to measure, not the specific damping capacity, but the actual energy dissipated per cycle. Under these circumstances, the comparison of the static with the dynamic tests would involve no difficulties in interpretation of the data.

ACKNOWLEDGMENTS

This work was carried out in preparation for a thesis for the Master of Science degree at Massachusetts Institute of Technology.

The author wishes to express his appreciation to Prof. A. V. de Forest of the Massachusetts Institute of Technology for assistance in the course of this work; to the Bakelite Corporation and to Bakelite Limited of England for the supply of materials; and to the London County Council for the award of a Robert Blair Fellowship, enabling this work to be undertaken.

Design Data

It is important that the data contained in technical papers be made readily available to designing engineers. In order to satisfy these needs of industry, this section of the JOURNAL will include a concise presentation of data and information drawn chiefly from papers previously published by the Applied Mechanics Division of The American Society of Mechanical Engineers.

The first series dealt with the subject "Strength of Materials" and the present series will cover the subject "Vibration." The data have been prepared by a subcommittee of the Applied Mechanics Division (J. Ormondroyd, chairman), under the general guidance of S. Timoshenko.

The first article, which follows, is by J. Ormondroyd. This treats of the systems with one degree of freedom and gives a list of symbols and definitions which will be adopted in future articles of the series.

Vibration Problems

Systems of One Degree of Freedom and Basic Symbols and Definitions

Part I

By J. ORMONDROYD,[1] ANN ARBOR, MICH.

THE problem of vibration in machines and structures of engineering interest is merely a special problem in dynamics. If the motion of every particle in the system could be specified for every instant, then a great number of facts of technical interest could be deduced. For instance, the distribution of stresses in the system is known when the motions of all the particles are specified, and the possibilities of kinematic interference are indicated by the same data.

The number of independent coordinates needed to specify completely the configuration of any mechanical system at any instant gives the number of degrees of freedom of the system. From this it follows that if one wishes to describe accurately the motion of every particle in any system, the number of degrees of freedom is infinite. However, for practical purposes, it is possible to imagine systems approximately equivalent dynamically to the system under consideration which have a small number of degrees of freedom. The criteria used to determine how many degrees of freedom to ascribe to any system under discussion are practical in nature. For instance, some, or most, of the possible motions in the system may be so small that they are not of practical interest. Some or most of the motions of the particles in the system may be practically similar permitting such particles to be lumped into a single body which can be considered to be rigid. The range of frequencies of the disturbing forces or torques may be so small that only one, or at most a few, of the natural frequencies of the system can ever be involved in resonance. All groups of particles in the system which cannot possibly undergo significantly large distortions under the magnitude and frequencies of the applied forces or moments may be considered single bodies, thereby reducing the number of degrees of freedom necessary to consider. These practical considerations which permit the creation, in imagination, of systems of approximate dynamical similarity to the actual systems which concern the engineer lead to the concepts of lumped masses which are absolutely rigid—connected by members which are flexible but have no mass. It is with such systems that most of the design-data papers to be published will deal. These systems give first approximations to the actual motions. Usually the motions predicted by using such approximate systems are close enough to the actual motions to satisf y all practical demands.

In some systems a second approximation can be found by taking into account the mass which the elastic members obviously possess. This is necessary only when the flexible members have masses which are appreciable in magnitude in relationship to the masses of the parts of the system which are considered as rigid bodies.

Finally there are many systems of practical interest which have such simple shapes that they can be considered as systems possessing an infinite number of degrees of freedom. For these there are the conceptual and mathematical tools which make it possible to do so. The vibration of strings, simple beams, plates, shells, and infinite and finite bodies of gases and liquids all come in this class.

SYSTEMS OF ONE DEGREE OF FREEDOM

A surprisingly large number of practical vibration problems which arise in the mechanisms and structures designed by engineers can be treated with a sufficiently high degree of accuracy by imagining the actual system to consist of a single rigid body, the motion of which can be described by a single coordinate. In reality the simplest imaginable system always consists of two bodies—the body the motion of which is of interest and the immediate surroundings of this body. It is assumed that the surrounding body is so large and rigid that the forces acting on the first body which react on the surrounding body do not move or distort the surrounding body. The motions measured in the first body are measured relative to the fixed surrounding body.

The problem of treating such a simplified system is fourfold. The first part consists in deciding what part of the system is the rigid body and what parts are the flexible members. The second part consists in calculating the values of the dynamic specifications of the rigid body and flexible parts. The third part consists in writing the equations of motion of the equivalent system. Finally, the fourth part consists in solving the equations. The first two steps require judgment and experience which come with practice, that is, with the repeated process of assuming equivalent systems, predicting their motions and checking the pre-

[1] Professor of Engineering Mechanics, University of Michigan.

dictions against actual measurements on the real systems. The last two steps merely consist in applying procedures which were worked out long ago by physicists and mathematicians. The real work lies in the first two stages, while the last two stages are mere mechanical applications of recipes, so to speak.

The first two stages can never be avoided or changed, but the last two stages can be varied. For instance, there are many approximate methods, numerical and graphical in nature, which can be used in the place of the classical procedure previously outlined. Methods using the kinetic and potential energies of the system are frequently used in the place of the last two stages.

Before proceeding to any detailed useful results, a table of symbols which will be used in the subsequent papers is given. A list of definitions which are necessary in treating vibrations is also appended.

Nomenclature

Quantity	Symbols	Units
Force	P, X, Y, Z	lb
Moment	M, T, M_x, M_y, M_z	lb-in.
Amplitude (linear)	A, B, x_0, y_0, z_0	in.
Amplitude (torsional)	$A, B, \theta_0, \varphi_0$	radians, deg
Circular frequency	ω	radians per sec
Natural circular frequency	p	radians per sec
Frequency	f	cycles per sec
Natural frequency	f_c	cycles per sec
Period	T	sec per cycle
Cycles per second	$\sim$	cycles per sec
Wave length	λ	in.
Wave velocity	v	in. per sec
Linear displacement	x, y, z	in.
Linear velocity	$v, \dot{x}, \dot{y}, \dot{z}$	in. per sec
Linear acceleration	$a, \ddot{x}, \ddot{y}, \ddot{z}$	in. sec^{-2}
Torsional displacement	$\theta, \varphi, \alpha, \beta, \gamma$	radians
Torsional velocity	$\omega, \dot{\theta}, \dot{\varphi}, \dot{\alpha}, \dot{\beta}, \dot{\gamma}$	radians per sec
Torsional acceleration	$\alpha, \ddot{\theta}, \ddot{\varphi}, \ddot{\alpha}, \ddot{\beta}, \ddot{\gamma}$	radians sec^{-2}
Mass	m	lb sec^2 in.$^{-1}$
Mass density	ρ	lb sec^2 in.$^{-4}$
Weight per unit volume	γ	lb in.$^{-3}$
Spring constant (linear)	k	lb per in.
Spring constant (torsional)	k	lb-in. per radian
Mass moment of inertia	I	lb in. sec^2
Moment of inertia (geometrical)	I	in.^{4}
Polar moment of inertia (geometrical)	J	in.^{4}
Damping constant (linear)	c	lb sec in.$^{-1}$
Damping constant (torsional)	c	lb in. sec
Critical damping constant (linear)	c_c	lb sec in.$^{-1}$
Critical damping constant (torsional)	c_c	lb in. sec
Logarithmic decrement	δ	
Harmonic number	n	
Order number	m	cycles per rev
Radius of gyration	k	in.
Acceleration of gravity	g	in. sec^{-2}
Static deflection	δ_{st} or Δ	in.

Definitions

Note: In these definitions the motion of a particle has usually been specifically in mind. However, the definitions hold also for torsional motion if "angular rotation" is substituted for motion and "rotating body" is substituted for particle or point.

Simple Harmonic Motion. Any motion which can be described by an equation similar to $x = A \cos \omega t + B \sin \omega t$ is simple harmonic motion. The displacement x described by this equation is best imagined as being represented by the motion of the end

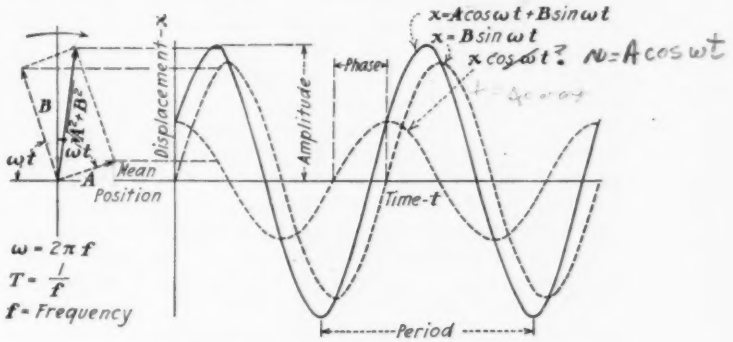

Fig. 1 Simple Harmonic Motion

of a rotating vector projected on the x-axis. The length of the vector is $(A^2 + B^2)^{1/2}$ and it is rotating with a constant angular velocity of ω radians per sec.

Cycle. Any simple harmonic motion repeats itself in every respect at regular and constant time intervals. This is true no matter where the time intervals are started. One complete progression of all the possible positions of the moving particle is called a cycle.

Period. The time interval taken to complete one cycle of motion is the period.

Frequency. The number of complete cycles of motion per unit of time is the frequency. This is the reciprocal of the period.

Amplitude. The extreme distance from the mean or middle position in any simple harmonic motion is the amplitude.

Range. Distance between positive and negative extreme positions—distance from crest to trough—is the range. Sometimes range is called *wave height* and *double amplitude.*

Phase. The phase of a simple harmonic motion at any instant is the fraction of the whole period which has elapsed since the moving point last passed through its mean or middle position in the positive direction. The phase of the motion at any time t, measured from the positive passage through the mean position, is t/T.

Phase Angle. Two simple harmonic motions having equal frequencies can be said to have a phase relationship if one wave leads the other in time. The lead is measured by the difference in time τ between the positive passages of both waves through their mean positions. The phase angle between the two waves is then $\omega\tau$.

Periodic Motion. The displacement x of a particle from a mean position is periodic if its magnitudes repeat themselves for values of time t differing by a constant. Simple harmonic motion is the simplest possible periodic motion.

Harmonics. All periodic motions which are not simple harmonic motions can be considered as combinations of simple harmonic motions having frequencies which are exact integer multiples of the fundamental cyclic frequency of the periodic motion. Such motion can be described by equations of the form

$$x = A_0 + \Sigma A_n \cos n\,\omega t + \Sigma B_n \sin n\,\omega t$$

Here ω is the angular velocity of the vector whose projection represents the wave of fundamental cyclic frequency, n is the harmonic number, $n\omega$ is the angular velocity of the vector whose projection represents the wave of the nth harmonic; n does not necessarily have to take on all of the integer values from 1 to ∞, nor do the values of n have to be contiguous integers.

Beats. When two simple harmonic motions with frequencies which are nearly equal combine, the resultant motion gives rise to the phenomenon of "beats." The resultant motion may or may not be strictly periodic depending on whether the frequencies are commensurable or incommensurable. No matter which of these cases exists, the envelope of the motion varies from a maximum to a minimum in a cycle which has a definite period $T = T_1T_2/(T_2 - T_1)$. The envelope of the motion is a periodic function with a frequency $f = f_2 - f_1$.

Damped Simple Harmonic Motion. This motion has all the characteristics of simple harmonic motion except that the amplitude is variable and is a continuous function of time. The amplitude may be continuously decreasing or increasing depending on whether the damping is positive or negative.

Logarithmic Decrement. The logarithm of the ratio of any two successive excursions from the mean position of any damped simple harmonic motion taken at a time interval equal to the period of the motion is the logarithmic decrement. Usually it is taken as the logarithm of the ratio of two successive maximum excursions from the mean position.

Aperiodic Motion. Motion which takes place in one direction only is aperiodic motion.

Vibration. Any periodic motion is a vibration. Frequently vibration is defined as a small periodic motion. But "small" used in this sense is a relative term. In a vibrating system a "small" relative motion exists between the various parts of the system when the motions have maximum excursions from their mean positions not exceeding a small percentage of the important linear dimensions of the system. The motion is also "small" when the proportional limits in tension, compression, or shear stresses are not exceeded in the elastic members of the system during the motion.

Free Vibration. Vibration which takes place when no external force is acting on the system. If the system is distorted from equilibrium configuration and then released, it will vibrate with free vibration. If any part of the system is struck a blow, the system will vibrate freely. Free vibration exists when the forces acting on the system arise solely from motion of the system itself. The frequencies of the free vibrations are fixed functions of the mass, elastic, and damping properties of the system itself. They are called natural frequencies.

Forced Vibration. Vibration which takes place under the excitation of external forces is forced vibration. External forces in any system are forces which have their reactions acting on bodies which are not parts of the system isolated for study.

Transient State. Whenever any changes of the mass or elastic properties in the system or in the magnitude or the frequency of the external exciting force on the system take place, a free vibration ensues which is superimposed on the existing state of motion. In all actual systems this free vibration gradually dies out because of damping. During the existence of the free vibrations having the natural frequencies of the system, the system is said to be in a "transient state" of motion.

Steady State. Forced vibration which takes place when neither the system itself nor the exciting forces are changing and after any transient states have died out or before they have started.

Natural Frequency. The frequencies of any free vibrations of a system that has been disturbed from its equilibrium position and then left undisturbed by any external force are called natural frequencies. For any particular system they have definite constant values.

Resonance. When a system is excited by a periodic external force which has a frequency equal to or nearly equal to a natural frequency of the system, the ensuing vibratory motion becomes relatively large even for small amplitudes of disturbing force. The system then is in a state of resonance.

Critical Speed. Any speed of operation of a machine at which the periodic disturbing forces inherent in the operation of the machine give rise to the largest or most dangerous vibratory responses in the parts of the machine. A critical speed exists when the frequency of the disturbing force is equal to or nearly equal to a natural frequency of the machine.

Wave Length. When regular trains of waves exist in some continuous medium, the shortest distance between contiguous wave peaks is called the wave length.

Wave Velocity. When waves move in some continuous medium (sound waves in air), the velocity of advance of any particular wave peak is the wave velocity.

Order. In many rotating machines the vibration frequencies encountered are simple multiples of the rotation frequency. The number of complete cycles of vibration per revolution of the machine is called the "order" of the vibration.

Major Critical Speed. A major torsional critical speed occurs in a multicylinder engine whenever the harmonic torques of the same frequency acting at the different cylinders are in phase. The harmonic torques with frequencies which are multiples of the firing frequency give rise to major critical speeds. Major critical speeds cannot be avoided or modified by changing the engine firing order.

Minor Critical Speed. A minor critical speed occurs in a multicylinder engine whenever the harmonic torques of the same frequency acting at the different cylinders are out of phase. The harmonic torques with frequencies which are not multiples of the firing frequency give rise to minor critical speeds. Alteration of the firing order can sometimes change the magnitude of motion in a minor critical speed.

"Major" and "minor" are somewhat misleading terms since they do not necessarily indicate the relative violence of motions in all cases. Minor critical speeds can be just as dangerous as major critical speeds.

Node. A point (line, plane, volume) in a vibrating system which has no vibrational motion. The node moves at the average velocity of the system and does not take part in the periodically changing motion.

Loop. A point (line, plane, volume) in a vibrating system which undergoes maximum motion. There may be several loops in the system. A loop is contrasted to a node. A loop moves with both the average velocity of the system and the vibratory velocity superimposed.

Mode of Motion. The mode of a vibration is characterized by the number of nodes which exist in the system at the various natural frequencies. For instance, the "two noded mode of motion" exists at resonance with that natural frequency which gives rise to two nodal points (lines, planes, volumes) in the system.

Discussion

The Effect of the Speed of Stretching and the Rate of Loading on Yielding of Mild Steel[1]

R. K. Bernhard.[2] This paper describes "the effect of the speed of stretching and the rate of loading on the yielding of mild steel," mainly from the point of view of the material itself. It might be of interest to treat the subject more dynamically,[3] in other words, discuss the change of equilibrium between specimen and testing machine or natural frequency of test machines and accuracy of indication in high-speed tests with respect to the determination of yield points.

In high-speed testing of essentially the same material, different results may be obtained depending upon whether the material is tested in a massive or in a light testing machine. Furthermore, the stress-strain diagrams of certain materials indicate peculiar forms near the yield point, which in some cases, may not be dependent upon the qualities of the tested material alone.

(1) *Static System.* Any testing machine, for example, with a hydraulic cylinder, may be considered as a system composed of masses and springs. Masses are the frame of the machine (the crosshead, etc.) while springs with a definite elastic constant represent the test specimen and the hydraulic medium. At any moment there must be equilibrium between the summation of the elastic forces of the springs and the load on the ram of the machine.

In the case of a testing machine having a low elastic constant, a very small decrease of load will result with the increase of strain; a high elastic constant, on the other hand, will result in a considerable decrease in load with increase of strain. When plastic flow ceases, equilibrium between the two elastic forces (specimen and pressure medium) may be restored and the point of equilibrium again rises as soon as the pressure pump starts to force new liquid into the cylinder. It must be borne in mind, however, that with decreasing tension in the specimen, the plastic flow will also cease.

Any rapid flow gradually changes into some kind of creeping flow before equilibrium is finally achieved. Hence, such drop in the load-deformation diagram, due to plastic flow, may be independent, in certain cases, of the quality of the tested materials, in high-speed testing.

(2) *Dynamic System.* The plastic flow or any pressure changes in the cylinder may take place very suddenly and the indicating device of the testing machine must follow these rapid changes immediately in both coordinates, load and deformation. It is well known that as soon as rapid changes come into consideration, the accuracy of any indicating device depends on the natural period of the whole vibrating system.

Any fluctuations during the test having a frequency of more than one tenth of the frequency of the machine will cause incorrect indications, assuming for simplicity that only vibrations of a sine form with a small damping factor come into consideration. This indicates also that different values for the upper and lower yield points, independent of the quality of the tested material and due to rapid changes of plastic flow near to these yield points, may be found in certain cases of high-speed testing.

(3) *Effect Upon Yield-Point Determinations.* The surplus in tension at the upper yield point is some kind of delayed phenomenon. Once plastic flow of the material in the specimen has started, the further shape of the diagram depends, at least to a certain amount, upon the character of the test machine. If the elastic constant of the test machine is low, any lower yield point will be suppressed, as the elongation of the test specimen produced by plastic flow means no decrease in tension for the testing machine itself. A very high elastic constant of the testing machine, however, will produce the well-known fluctuations (leaping effect).

A similar result will be produced if the test specimen is long and has a low elastic constant, thus causing a heavy drop in the diagram. Consequently, a very short and rigid specimen may indicate no lower yield point at all.

(4) *Conclusions.* The conclusion is accordingly reached that the upper and lower yield points are associated, also, with the characteristics of the testing machine and are to a certain degree independent of the quality of the material, and that the form of the specimen may be in *specific* cases of high-speed testing, secondary.

A. V. de Forest.[4] The method of test chosen by the author prevents any possibility of investigating the lower yield point but gives significant information as to the effect of rate of loading under relatively slow loads. Unfortunately, it appears that the upper yield point is largely determined by test conditions and is thus difficult to appraise as a true mechanical property of the material itself. The author has emphasized the lack of information as to the actual gage length over which the yield strain is taking place, a most important point. It is to be hoped that some method of measurement can be developed to clarify this point.

A reference is made to the stress-concentrating effect of the notch existing at the junction of the strained and unstrained metal. While there is a mechanical notch at this point, it is believed that the real notch effect is a metallurgical one rather than a mechanical one and that the flowing layer between the stressed and unstressed metal is the crux of the problem. The character of this layer approximates the out-moded Beilby layer of viscous fluid. The strength of the layer is greatly influenced by the rate of deformation, the temperature of the test piece which itself is a function of the rate of deformation, and hardens or sets at a rate greatly dependent on the particular quality of steel involved. In other words, the rate of strain aging is the most important part of the phenomenon.

One of the convolutions of curve *F*, Fig. 4, illustrates discontinuities in the stress-strain diagram which have been noticed in many other cases. It is believed to be important as showing that, while the singular yield point in steel is the one primarily of interest to engineers, any explanation of the yield-point phenomenon must also be capable of explaining diagrams in which a multiplicity of yield points are found throughout the flow portions of the diagram.

---

[4] Professor, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

JOSEPH WINLOCK[5] AND R. W. E. LEITER.[6] The author lays great emphasis on the effect of a concentration of stress and a resulting high strain rate. It is agreed that this is of great importance, but not that he is justified in attributing the cause of the phenomena simply to a concentration of stress. Are there not similar stress concentrations in a tensile specimen of aluminum or copper? Yet no similar yield-point phenomena are manifested by these metals. Again, if a high concentration of stress is produced during a tension test of aluminum or copper by

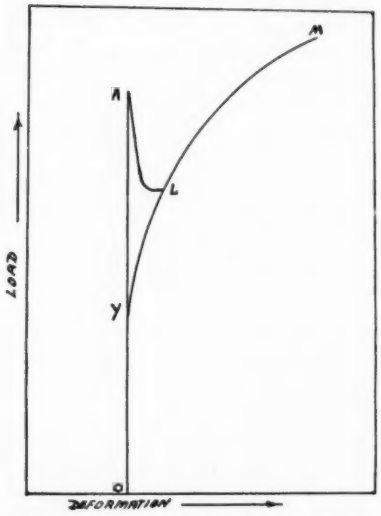

FIG. 1 LOAD-DEFORMATION CURVES FOR METALS WHICH DO AND DO NOT SHOW YIELD-POINT PHENOMENA

suddenly putting a notch in the specimen, a drop in the registered load occurs, but there is no yield-point elongation; that is, a localized elongation which widens until the whole gage length is affected does not occur under these circumstances.

The writers believe that the inordinately high elastic resistance of low-carbon steel, before plastic deformation is initiated, and the comparatively low resistance to plastic deformation, once this has started, are the causes of the phenomena; and that this conception is essential in order to obtain a true picture of what is occurring at the yield point and during the yield-point elongation. Such a conception appears to be lacking in the author's paper.

In order to make this point clear, the writers would like to refer to Fig. 1 of this discussion. The curve *OYLM*, Fig. 1, is the load-deformation curve of metals like aluminum and copper which do not show the yield-point phenomena. As will be noted, the curve is smooth even though there undoubtedly are concentrations of stress during the deformation. On the other hand, low-carbon steel does not yield at the load *Y*, but overshoots this load and yields only after the excessively high load *A* has been reached. (The difference in modulus of low-carbon steel and aluminum and copper is omitted for the sake of clearness). At the instant yielding occurs, the resistance of the metal is believed to be only the load *Y*. As a result of this, an extremely localized yielding occurs accompanied by a very high strain rate which produces a high concentration of stress in the metal immediately adjacent to the stretcher strain. The remaining portion of the load-deformation curve takes the shape shown by *ALM* simply as the result of the several conflicting conditions now existing: (1) The high elastic strength of those parts of the specimen not yet plastically deformed; (2) the low resistance of the metal at the instant plastic deformation occurs; and (3) the work strengthening of the plastically deformed metal.

As the author points out (in conclusion 6) the rate of work strengthening during the yield-point elongation is unknown, but, as the writers point out,[7] a continuation of the curve *CD* in Fig. 2 of his paper seems to us to be justified. The reasons for this conclusion are: (1) The slower the speed at which the test is carried out, the shorter the yield-point elongation and the lower the load at which the horizontal portion of the load-deformation occurs. (There is, however, a yield-point elongation at even the lowest possible speed of deformation.) At decreasing testing speeds, a continuation of the curve *CD* approaches the elastic portion of the curve, and even though its position is lowered, its general shape is not changed. (2) Hardness readings taken at the bottom of Lüders lines formed at different speeds show the hardness to be increasing in a normal manner and the shape of the curve is similar to that of *CD*. (3) An extremely slight amount of cold rolling removes the yield-point phenomena entirely and produces a condition of plasticity throughout the specimen. Test specimens taken from such material show a low yield point, i.e., the load *Y* in Fig. 1 in this discussion, and a load deformation curve like that of *OYLM*.

AUTHOR'S CLOSURE

As Professor Bernhard points out, the effect of the rigidity of the testing machine upon the resulting upper and lower yield points is of great importance. The work of Welter, Siebel, and others listed in references (6, 7, 8) of the paper shows this quite well. However, it seems evident that changing the elasticity factor of the testing machine can only change the rate of loading in the elastic range and the speed of deformation after yielding starts. The point, which the author would like to make, is that, when the speed of deformation and the stress concentrations are taken into account, the differences due to the elasticity factor of the testing machine tend to disappear.

In the constant-load-rate tests reported in the paper, the vibrations and inertia forces were small and hence were neglected. In the most rapid tests, the large moving weight dropped approximately two inches in one second during the yield-point elongation so that the acceleration was small compared to that of gravity.

Two statements of Professor Bernhard seem to conflict with each other: First, he says that, in a machine having a low elastic constant, a very small decrease in load will result from a sudden increase in strain while, in a machine having a high elastic constant, there will be a considerable drop in the load with a similar increase in strain. Later, he states that, if the test specimen is long so that it has a low elastic constant, there will be a heavy drop in the diagram. If the specimen is short and rigid there may be no indication of a lower yield point at all. The first statement seems logical and is in agreement with the results of the workers to which reference has already been made. If this is the case, however, it is difficult to understand how the latter statement can also be true. How can a low elastic constant in a test specimen cause a large drop in load at the yield point, when a low elastic constant in the testing machine tends to lessen this drop of load? Of course, if the properties of mild steel were such that a sudden increase in strain occurred simultaneously throughout the length of the test specimen, then a long bar would probably show a greater drop in load than a short bar. Actually, mild steel deforms locally and the elastic deflection of the remaining elastic portion of the long bar would have the same effect as elastic deflections in the testing machine. Therefore, a specimen with a

[7] "Some Observations on the Yield-Point of Low-Carbon Steel," by Joseph Winlock and R. W. E. Leiter, presented at 1938 Annual Meeting AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

low elastic constant should cause a smaller or, to be more exact, a less rapid drop in the load.

Professor de Forest brings out the fact that the time t may become an important variable in describing the properties of mild steel. This becomes necessary whenever changes, due to time alone, such as age hardening or annealing take place. Usually, when the effect of strain aging appears in the stress-strain diagram of mild steel, it shows up in that portion of the curve beyond the yield-point elongation. While the localized yielding is spreading along the length of the bar, the time that any given element of material is taking part in the yielding is rather short. Any aging, which might affect the yield point or yield-point elongation, would have to take place during the time that the wave of yielding was sweeping over the element in question. This time, although short, may still be important. Part of the yield-point phenomena may yet be explained in terms of strain aging.

With regard to the discussion by Messrs. Winlock and Leiter, concerning the cause of the yield-point phenomena, it may be well to recall that the intention of the paper was to discuss the influence of certain mechanical factors upon the yield point and in particular to show how they affect the stress-strain diagram. The reason behind the localized yielding in the material was not discussed and is not known so far as the author is concerned. It is granted that mild steel is weaker in the initial plastic region than in the elastic region, but the phenomena will probably not be fully understood until it is known what kind of a breakdown occurs which prohibits a gradual transition from the elastic to the plastic region.

In conclusion, the author would like to emphasize a few points on the ever-present question of whether the yield-point phenomena in mild steel are properties of the material or of the testing machine. Localized yielding and the apparent instability of the initial plastic flow definitely are properties of the material itself. This type of yielding occurs regardless of whether the load drops or increases. The shape of the standard recorded load-mean elongation curve (to be distinguished from the real stress-strain diagram) and the manner in which the load behaves after yielding starts are due largely to the characteristics of the testing machine, as has been shown by several experimenters. The reason why one material can accommodate itself to differently shaped stress-strain diagrams is that the actual stress in the yielding layers is not a function of strain alone but also depends upon the speed of deformation and possibly upon a time factor.

Steady Oscillations of Systems With Nonlinear and Unsymmetrical Elasticity[1]

R. K. Bernhard.[2] The amplitude-frequency curve as shown in Fig. 28(*a*) has been derived mathematically by the author and fills the gap between theory and practice in an ingenious way.

Curves with the same characteristic form have been obtained by actual measurements, indicating the presence of nonharmonic mechanical vibrations. Two examples of such curves may supplement the author's paper and emphasize the practical importance of analogous states of unstable equilibrium in the field of the structural engineer. Investigations have been made by the writer to determine the effect of unbalanced parts of counterweights of driver axles of steam locomotives passing bridges at critical speed.

[2] Professor and Head of Department of Mechanics and Materials of Construction, The Pennsylvania State College, State College, Pa.

(1) For a simple girder a series of resonance curves, Fig. 1, has been measured, showing the relation between discord (i.e., the ratio between exciting frequency and natural frequency of the girder) versus the corresponding excited amplitudes of the girder for varying magnitudes of the exciting forces. The lowest curve No. 1 is measured with only an exciting force of the unit 0.25, in order to produce a maximum amplitude within the range of a linear spring constant and a constant friction. Hence, this particular curve No. 1 still has a normal form. However, the next curve No. 2 shows a slight tilting effect, which appears to be substantially increased in curve No. 3 measured for an exciting force with the unit 1.0. The considerable increase in damping is shown by the wider gap at the top of curve No. 3. This phenomenon of increased damping effect is still more striking in

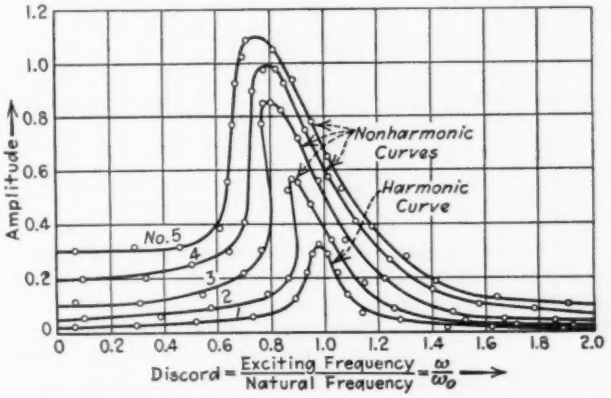

Fig. 1 Resonance Curves for Nonharmonic Vibrations (Amplitude versus discord for varying magnitudes of the exciting forces.)

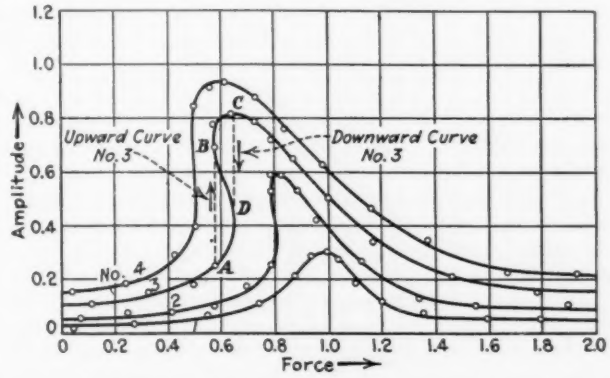

Fig. 2 Resonance Curves for Nonharmonic Vibrations (Amplitude versus force for constant exciting frequency.)

curve No. 4. Furthermore, the maximum amplitudes have increased only a relatively small amount, though the exciting force has double the size as shown in the increase of static amplitude from 0.1 to 0.2 (discord $\frac{\omega}{\omega_0} = 0$). The tilting of the three curves Nos. 1, 2, and 3 in the direction of lower frequencies is a characteristic sign of nonharmonic vibrations. Finally, in curve No. 5 this tilting effect gradually disappears, caused by the relatively larger values of the damping, which simultaneously prevents the building up of higher amplitudes. However, the broadening of the range of resonance, combined with the steep incline in the rising branch, produces an unsymmetrical shape, also, of curve No. 5.

(2) In Fig. 2, a series of similar resonance curves for a simple girder has been measured, showing, however, the relation be-

tween exciting force versus the amplitudes of the girder. Furthermore, a constant exciting frequency has been applied, imitating a constant speed of the passing loads (locomotives). The force = 0 means that only the elastic force of the vibrating girder is acting. All curves show analogous forms as obtained in Fig. 1. Again, a certain range of curves, Nos. 2 and 3, shows a pronounced tilting effect. With rising forces, an abrupt step-up from small to higher amplitudes takes place, indicating a state of unstable equilibrium (see curve No. 3, dotted line *A–B*); with decreasing forces, a similar abrupt step-down from high to low amplitudes takes place, however, at a point of larger forces (see curve No. 3, dotted line *C–D*) as compared with the step-up.

All these curves have been measured in applying the method of induced vibration, which has been described in previously published papers.[3]

Results. Some of the conclusions which can be drawn from these investigations may be summarized as below. The writer intends to give a more detailed report on this particular subject in a subsequent paper.

1 The tilting effect, as indicated in the amplitude-discord and amplitude-force resonance curves for vibrating structures shows obviously that nonharmonic vibrations are present in practical cases.

2 The nonharmonic vibrations cause an abrupt jump in the magnitude of the deflections of the structures, due to nonlinear elasticity and nonlinear damping.

3 A new structure, with still rigid riveted connections, shows a relatively small nonharmonic effect and hence, will vibrate smoothly; an older, worn-out structure, with more or less loosened connections, will produce the tilting effect, and hence, will endure higher dynamic impact stresses.

4 When computing the dynamic influence on bridges, which carry loads of passing steam locomotives with unbalanced parts of their counterweights, the classic theory of pure elasticity will yield only a relatively rough approximation.

R. P. Kroon.[4] Free oscillations of nonlinear systems without damping can be found by simple integration. The author proposes to take care of forced and damped vibrations by lumping the exciting forces and friction forces together with the spring force into a general restoring force. Therewith the problem is reduced to that of an artificial free vibration.

The exciting force being a function of time and the friction force depending on velocity, some way has to be found to transform these into functions of displacement like the spring force. To do this, it is proposed to assume for a first approximation that "the displacement curves of the free motions and that of the forced motion at the same amplitude are identical" and that "the frequency of the force is the same as that of the free motion."

These assumptions are obviously good for forced oscillations at resonance (where exciting and damping forces are small compared with elastic forces and inertia forces which govern the free vibration). How well they work in other cases is indeed remarkable. The writer cannot resist demonstrating this for the case of a simple linear undamped system.

In a linear system with one degree of freedom x, the elastic force can be written as

$$E = kx \quad [1]$$

and the free harmonic motion will be expressed as

$$x = x_0 \cos \sqrt{\frac{k}{m}}\, t \quad [2]$$

(k = spring constant, m = mass, t = time.)

For the forced vibration a periodic exciting force

$$F = \pm F_0 \cos \omega t \quad [3]$$

is now assumed. The two signs are to indicate that F can be either in or out of phase with the motion.

F_0 being given, the value of the impressed frequency ω is not prescribed at first. Rather, the problem becomes: What will be the value of ω at which an amplitude x_0 can be sustained?

According to the paper ω is first assumed to equal the natural frequency of the system. The exciting force is then

$$F = \pm F_0 \cos \sqrt{\frac{k}{m}}\, t \quad [4]$$

In view of Equation [2] this can be written

$$F = \pm F_0 \frac{x}{x_0} \quad [4']$$

The elastic force E and the impressed force F are now lumped into a "net restoring force" R

$$R = E - F = kx \pm F_0 \frac{x}{x_0} \quad [5]$$

This new restoring force will be made the elastic force in an imaginary "free vibration," which would be harmonic and have the form

$$x = x_0 \cos \sqrt{\frac{k \pm \dfrac{F_0}{x_0}}{m}}\, t \quad [6]$$

the circular frequency being

$$\omega = \sqrt{\frac{k \pm \dfrac{F_0}{x_0}}{m}} \quad [7]$$

This is already the expression for the frequency of the exciting force necessary to create a forced vibration of amplitude x_0. According to the paper Equation [6] should be used as a second approximation, instead of Equation [2] and should give the exciting force Equation [3] the frequency just found in Equation [7]. It is obvious that, from Equation [4'] on, the equations remain unaltered so the answer is final. The solution Equation [7] is, of course, the equivalent of the more familiar form

$$x_0 = \frac{F_0}{k - m\omega^2}$$

Author's Closure

Professor Bernhard, by offering data on the actual occurrence of nonharmonic vibrations in practice, contributes a welcome point in his comment. A particularly interesting feature of his curves is their behavior on the fringes of the unstable region to the left of the resonance peaks. Mr. Kroon's contribution adds clarity to the paper in another detail. To both commentators the author wishes to express his thanks.

Book Reviews

Vibration

EINFÜHRUNG IN DIE TECHNISCHE SCHWINGUNGSLEHRE. By Dr. Karl Klotter. Volume 1. Julius Springer, Berlin, 1938. Paper, 6¾ × 10¼ in., vii and 206 pp., 208 figs., 18 rm.

REVIEWED BY FRANK M. LEWIS[1]

THE FIRST of the three volumes of this work is devoted entirely to the study of the single-degree-of-freedom system. Subsequent volumes will respectively consider systems of several, but a finite number of, degrees of freedom and distributed systems.

To a large extent any new book on vibration must cover problems made familiar by many previous texts, and criticism can be made only of the manner of presentation. About half of the text is devoted to the classical problem of the free and forced vibration of the single-degree-of-freedom system and here the presentation must be considered excellent. Some forty pages treat the forced vibration of the linear system with a thoroughness which certainly exhausts the subject, and possibly the reader also.

Here free use is made of complex notation and the methods parallel those developed in the theory of alternating currents. Presentation of results is both by the familiar resonance curves and by a method used in electrical engineering in which families of curves represent the termini of the displacement or other vectors.

The remainder of the text largely considers systems which are nonlinear in their damping and spring constants and a considerable variety of problems is given. Systems with nonlinear and variable mass are not discussed. The treatment of forced vibration of systems with nonlinear springs is that of Den Hartog and Heiles, the recent exact relation of Rauscher evidently not having come to the author's attention before publication.

The case of accelerated vibration, i.e., passing through a critical, is discussed in abstract and the book concludes with a very brief discussion of self-sustained oscillation.

Fatigue of Metals

LA FATIGUE DES MÉTAUX. By R. Cazaud and L. Persoz; preface by A. Caquot. Dunod, Paris, 1937. Paper, 6½ × 10 in., viii and 190 pp., 121 figs., tables.

REVIEWED BY JOHN M. LESSELLS[2]

THIS SMALL book on fatigue of metals is of interest since while this subject has been intensely studied in other countries very few publications have come from French engineers. The purpose of the book is given in a note, sounded at the end of chapter one, commenting on the fact that certain phases of fatigue investigations have been badly coordinated, which has given rise, in certain cases, to contradictory results. An attempt is made in the book to present the results of the more important experiments, in review form, with a view to clarifying the existing data where doubt now exists.

The book contains eight chapters. The first is historical in character, and the following five chapters contain more or less well-known facts on the various theories of fatigue, testing machines used, and the results obtained. Chapter five contains data on the fatigue of nickel and nickel-molybdenum and other steels and is of interest because the fatigue strength is related to the microstructure. This is the first time that such a detailed effort has been made along these lines to correlate structure with fatigue strength. The subject of the fatigue of different kinds of jointed members, riveted, welded, brazed, is considered in chapter seven, while the last chapter is devoted to general conclusions. In the last chapter the data on allowable stresses, as contained in the published leaflets of the Verein deutscher Ingenieure, are discussed. In this regard it is to be regretted that the authors did not see fit to include and discuss the work of the Applied Mechanics Division on the subject as contained in the Design Data section of the JOURNAL OF APPLIED MECHANICS, September 1935.

The book is, however, of considerable interest and contains an excellent bibliography at the end of each chapter.

Fluid Mechanics for Hydraulic Engineers

FLUID MECHANICS FOR HYDRAULIC ENGINEERS. By Hunter Rouse, Assistant Professor of Fluid Mechanics, California Institute of Technology. First edition. Engineering Societies Monographs. McGraw-Hill Book Company, Inc., New York, 1938. Cloth, 6 × 9 in., xvi and 422 pp., 245 figs., and 6 tables, $5.

REVIEWED BY HUGH L. DRYDEN[3]

THE SUCCESS of modern fluid mechanics in providing an analytical approach to many engineering problems encountered in the design of aircraft has stimulated interest in fluid mechanics as a basic science and in its possible applications to other fields of engineering, in particular to hydraulics. Many American technical schools are experimenting with a basic course in fluid mechanics as a substitute for the traditional course in hydraulics, and a number of textbooks intended for use in this course have appeared recently. All encounter a fundamental difficulty which the authors have tried to meet in several ways.

In the present state of fluid mechanics, it is not possible to begin from fundamental principles and give a rational development of the theory of the varied phenomena encountered in nature. Rather one must recognize certain more or less typical phenomena, make simplifying assumptions which by rational analysis reproduce the phenomena. The selection of assumptions is based on the observed phenomena, and contradictory assumptions are used in different phenomena. Thus Bernouilli's theorem is of little use in studying the pressure changes in a closed conduit of constant cross section, since the kinetic energy is constant, and the fall in pressure corresponds to the loss of energy by friction. In flow in an open channel or in a conduit of variable cross section, Bernouilli's theorem may be very useful in estimating the much larger changes in static pressure, the friction being neglected. Such fickleness with regard to the applicability of a fundamental theorem is very confusing to the student. He has not only to become acquainted with certain groups of experimental data, and with certain basic principles of classical fluid mechanics, but also with many groups of often contradictory assumptions and the rational analysis of the con-

[1] Professor of Marine Engineering, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

[2] Associate Professor of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Mass. Mem. A.S.M.E.

[3] Chief, Mechanics and Sound Division, National Bureau of Standards, Washington, D. C. Mem. A.S.M.E.

sequences of the assumptions, and most difficult of all he must learn to recognize under what conditions a given group of assumptions is likely to yield a correct description of the behavior of the fluid.

Mr. Rouse meets this difficulty by assuming that the reader is already familiar, as a consequence of the traditional elementary course in hydraulics or otherwise, with the empirical facts of experience, i.e., with cavitation, secondary flow, general aspects of flow in closed conduits and open channels and over weirs, etc. His book is specifically addressed to graduate students and practicing engineers, offering a sound rational analysis of the observed phenomena.

The phenomena are classified in the main according to the property of the fluid of paramount importance. In part one, except for the last chapter, there is a selection from the classical treatment of the incompressible, nonviscous fluid of "all that is immediately useful or will have bearing upon later developments." For psychological reasons the term "ideal fluid" is not used, and the assumptions involved are not given prominence. There are practically no comparisons with experiment. The last chapter of this section very briefly describes the phenomena of compressibility of gases, cavitation of liquids, and flow separation as limiting the applicability of the "fundamental hydromechanics," in which density and weight are the only fluid properties considered.

Part two considers the mechanics of fluid resistance and occupies about one half the book. The discussion covers the Navier-Stokes equations, laminar flow, turbulence, boundary layer, flow around immersed bodies, in closed conduits, in open channels, and the transportation of sediment. The treatment is in general clear, accurate, and up-to-date. The author was evidently not familiar with the more recent work on the effect of initial turbulence on the drag of spheres and cylinders, and hence states that a particular curve for sphere and cylinder applies to "normal" conditions. This, however, is a relatively minor error in a book addressed to hydraulic engineers. Part three covers the mechanics of wave motion.

Throughout the book dimensional analysis holds a deservedly prominent place, and the discussion of the needed ingredients of judgment, common sense, and ingenuity in the use of this powerful method in the analysis of data and the planning of model experiments is especially to be commended. Unfortunately while these ingredients may be acquired or improved, they probably cannot be taught.

Vibration Problems in Engineering

VIBRATION PROBLEMS IN ENGINEERING. By S. Timoshenko, Professor of Theoretical and Applied Mechanics, Stanford University. Second edition. D. Van Nostrand Company, Inc., New York, 1937. Cloth 5¾ × 9 in., 462 pp., 229 figs., $5.50.

REVIEWED BY J. ORMONDROYD[4]

THERE existed in the early 1920's many treatises by physicists on the vibration of bodies producing sound, a complete theory of electric oscillations, a fairly large volume of scattered papers on mechanical vibrations and even several complete treatises on this subject in foreign languages. It is a somewhat lugubrious commentary on the state of mechanical-engineering education of that not too distant time when we consider that all this available material was almost a closed book to the profession as a whole. The number of mechanical engineers in the United States competent to solve any of the innumerable vibration problems in machinery existing at that time could easily be counted on the fingers of one man's hands.

[4] Professor of Engineering Mechanics, University of Michigan, Ann Arbor. Mem. A.S.M.E.

The times cried out for someone to transfer the existing state of knowledge concerning vibration to a level at which the mechanical engineer could comprehend it and use it. Timoshenko may be fairly said to have carried through this much-needed action when in 1928 he published his treatise on "Vibration Problems in Engineering." The first edition contained 346 pages of printed matter, 165 figures, and an appailing number of errata which slipped past in proofreading. This edition went through three printings in nine years and copies of it found their way into the libraries of a large number of practicing engineers. During these years several engineering schools introduced the subject into the curriculum, at least for advanced study, and the number of practicing engineers capable of handling vibration problems increased enormously.

When, in 1937, a second edition of this work appeared, the mechanical-engineering profession was prepared to welcome it and a younger generation of engineers existed which recognized its usefulness and possessed a background more suitable for understanding it. The second edition contains 462 pages of printed matter, 229 figures. It is comparatively free from the errata which marred the first edition. The material treated has been increased some 35 per cent. In the preface of the second edition the author outlines the principal additions as follows: "In the first chapter a discussion of forced vibration with damping not proportional to velocity is included, and an article on self-excited vibration. In the chapter on nonlinear systems an article on the method of successive approximations is added and it is shown how the method can be used in discussing free and forced vibrations of systems with nonlinear characteristics. The third chapter is made more complete by including in it a general discussion of the equation of vibratory motion of systems with variable spring characteristics. The fourth chapter, dealing with systems having several degrees of freedom, is also considerably enlarged by adding a general discussion of systems with viscous damping; an article on stability of motion with an application in studying the vibration of a governor of a steam engine; an article on whirling of a rotating shaft due to hysteresis; and an article on the theory of damping vibration absorbers. There are also several additions in the chapter on torsional and lateral vibrations of shafts."

These additions represent the results of important papers which have appeared in the technical literature since the first edition was printed. The citation of original papers on the subject in numerous footnotes forms a very valuable part of the treatise.

For those who are not familiar with the general contents of the volume it will be well to give a brief outline. The first chapter, containing well over 100 pages, discusses harmonic vibrations of systems having one degree of freedom. This chapter contains all the nomenclature, concepts, and mathematical methods which must be mastered by any engineer who expects to be reasonably effective in the field of vibrations. This chapter covers many problems of actual technical interest. The brief, qualitative discussion of self-excited vibrations at the end of this chapter will help to clarify many mysterious vibrations problems which confront engineers. The next two chapters discuss problems in systems of one degree of freedom which lead to nonlinear differential equations. Engineers who can handle the simple cases given in the first chapter will be especially pleased with the help and suggestion they receive in these two chapters in a field likely to be more baffling and elusive. Chapter 4 on systems with more than one degree of freedom opens with a clear, concise development of LaGrange's equations and includes, among many other good things, a discussion of stability of motion, a subject of supreme interest to all engineers dealing with control problems. Chapter 5 is a very practical chapter on tor-

sional and lateral vibrations of shafts carrying many rotors and supported in several bearings. This chapter is perhaps the most directly useful in the whole treatise. Chapter 6 deals with the vibration of continuous elastic bodies such as bars, membranes, and plates. This introduces the use of partial differential equations. Besides being useful for many practical problems, this chapter serves as an excellent introduction for those who wish to read intelligently volume 1 of Rayleigh's "Theory of Sound." All of the problems discussed in that volume—with the exception of the string, curved shells, and electrical oscillations—are treated in more understandable detail by Timoshenko in his chapter 6. The final chapter gives an exceedingly valuable description of all the common vibration-measuring devices—barring the strange omission of accelerometers and pressure indicators.

Readers of "Vibration Problems in Engineering" who are familiar with scientific history will realize that Timoshenko has done for the theory of mechanical vibrations what Rayleigh did for the theory of sound sixty years ago. They may also remember Rayleigh's quaint statement that "Without ears we should hardly care much more about vibrations than without eyes we should care about light." Timoshenko's treatise indicates that men, even if not blessed with ears, would still have many reasons for being interested in vibrations.

Timoshenko's "Vibration Problems in Engineering" bids fair to become a classic on the subject. It brings the general methods of the mathematical physicist down to the level of engineering comprehension by treating familiar problems in complete and particular detail.

Lubrication of Light Internal-Combustion Engines

LUBRICATION OF LIGHT INTERNAL-COMBUSTION ENGINES. By P. I. Orloff. Edited by N. R. Brilling, O.N.T. I., Leningrad, 1937. 462 pp., 336 figs.

REVIEWED BY GEO. B. KARELITZ[5]

THE AUTHOR says in his preface that he could not find in literature any treatise on the subject which he could use as a prototype. The best book in the field, to his knowledge, the German volume of E. Falz was unsatisfactory due to its "narrow practicality and absence of a theoretical background," and neglect of the vast experimental and theoretical works of American investigators. Mr. Orloff attempted to present a short encyclopedia of lubrication. He realized that this task was too difficult for one man.

The book is divided into seven chapters. In the first chapter the author presents a very able critical compilation of the existing knowledge on the behavior of the viscous oil film in a bearing. He uses Guembel's treatment of the subject but amplifies it by the recent work of the American and German authors. He gives therefore a rather complete picture of the hydrodynamical theory of lubrication in its present state. Whenever possible, he attempts to introduce practical coefficients which would bring together theory and practice into a closely knit fabric. It is evident from the treatment that the author had the opportunity to apply the theory and check it with practical designs, and thus acquired a critical approach to the curves and diagrams published by different authors. A section on rotating loads gives interesting considerations on the applications of the theory to bearings so loaded.

The material of Orloff's book is based on sources up to the year 1936. Some recent work which throws more light on lubrication phenomena is therefore not included, particularly that on internal-combustion engines such as the diagrams of Dennison for heavily loaded bearings, or the experiments of Bowden on surface temperatures of rubbing surfaces. However, together with the well-selected bibliography, this chapter is an interesting review of the hydrodynamic theory of lubrication as applied to bearing design.

The second chapter treats of design factors, running characteristics, and maintenance factors of a bearing. The problems met with are indicated and mentioned in a necessarily brief and general way.

The short third chapter mentions the tests used to determine the stability of lubricants and the means used to prevent oxidation and gumming of oils in internal-combustion engines. Chapter 4 gives a short survey of common bearing materials, based mostly on American practice. The compositions and mechanical properties of various babbitts and bronzes, and of several "oilless" bearing materials are listed.

Chapter 5 discusses rather briefly the application of ball, roller, and needle bearings to internal-combustion engines. All these chapters are of a descriptive character and serve only to call attention to important points which should be considered when designing a bearing.

Chapter 6 describes the general arrangement of the lubrication of the Kestrel motor of Rolls-Royce and of the Cyclone engine of the Wright Company. This is followed by a detailed description of the oil feed to main and connecting-rod bearings. The friction and lubrication of piston rings is mentioned just in passing. This short treatment is to be regretted since this is the most difficult phase of lubrication in internal-combustion engines, and since it appears from various reports that much experimental work is being done on this phase in the Russian research institutes. Auxiliary apparatus such as oil pumps, filters, packings are described.

Chapter 7 gives a short account of the theory of heat transfer and its application to the design of oil coolers for airplanes, with the bibliography of the subject.

The bibliography given in the appendix is a valuable feature of the book. It is well chosen and compiled. It compares with the bibliography given by M. D. Hersey in his recent book on lubrication. In general the book of Orloff could be well recommended to engineers if it were not written in Russian. It leaves the impression that the field remains open for a treatise which would cover the subject of lubrication and bearings in a way satisfactory to engineers.

Strength of Materials

STRENGTH OF MATERIALS. A First Course. By Norman C. Riggs, Professor of Mechanics, and Max M. Frocht, Associate Professor of Mechanics, Carnegie Institute of Technology. The Ronald Press Company, New York, 1938. Cloth, $5^3/_4 \times 8^1/_2$ in., xii and 432 pp., 454 illustrations, $3.75.

REVIEWED BY O. J. HORGER[6]

IT IS ALWAYS difficult to criticize a textbook prepared for a specific purpose and to meet the individual requirements of an author. So many books of this nature are being published that a book as a whole generally lacks in comparison with the outstanding books in their respective fields but contain valuable selections which may be considered as new contributions. In this latter respect the reviewer believes that the book under consideration excels in its introduction of the subject of photo-

[5] Professor of Mechanical Engineering, Columbia University, New York, N. Y. Mem. A.S.M.E.

[6] In charge of Railway Engineering and Research, The Timken Roller Bearing Company, Canton, Ohio. Mem. A.S.M.E.

elasticity. The authors present a legitimate case for the use of photoelasticity by both the student and the practicing engineer in the rational study of stress analysis. Few investigators have developed the technique exemplified in the excellent fringe-photograph reproductions given in this book. The authors use their photoelastic examples to show the fallacy of determining stresses from the usual calculations. There may be some question as to whether the discussion of photoelasticity occupies a disproportionate amount of the book as a first course in strength of materials. This could be argued in many ways but the reviewer feels that one cannot learn too early or too much about stress concentration, especially since economic necessity is requiring the use of lower factors of safety and lighter weights.

This book includes a treatment of continuous beams by the Hardy Cross method of moment distribution and omits the fundamental but cumbersome analysis of determining deflections by double integration. In a first-course text it would seem apropos first to give the student the necessary fundamentals and then proceed to short-cut methods. It is realized that books have size limitations but generally speaking authors make little use of footnotes and discussions in small type to which the student may refer for detailed analysis of many problems too lengthy for consideration in any one book. The use of many references in any textbook immensely increases its value not only to the student in later life who is already familiar with its contents but also to the practicing engineer. Exceptionally few problems presented in everyday experience have their solution in the elementary treatment appearing in the text, but footnotes more often permit the reader to cover the literature in a more comprehensive manner. Neglecting this comment, the usual essentials in a first course in the strength of materials are presented in this book and the illustrations and problems are numerous and well-arranged.

One may take exception to the omission of reference to alloy steels in the discussion of the properties of materials appearing throughout the book with the exception of brief mention under the subject of fatigue. A section on impact, dividing materials into "ductile" and "tough," is questionable as many materials exist which possess both these properties and it would appear that the term "brittle" is commonly applied to the author's expression "tough." No mention is made of Izod and Charpy impact test values or fact that a transition velocity of impact is characteristic of many materials above which velocity the impact strength is considerably reduced. The statement "the stress which will sustain four or five millions of cycles differs but little from the endurance limit" is not true in cases of corrosion fatigue, some nonferrous materials, some forms of stress concentration, and so-called delayed fractures in hardened steels.

Thermodynamics

TECHNISCHE THERMODYNAMIK. Part 2. By Fr. Bosnjakovic. Theodor Steinkopff, Dresden and Leipzig, 1937. 294 pages with 243 figures and 24 pages of problems and their solution. Price 19 rm.; in addition a portfolio of large charts, Price 8 rm.

REVIEWED BY JOHN A. GOFF[7]

THIS book constitutes a unique contribution to the literature of thermodynamics by presenting in one volume a complete and coherent treatment of the properties of binary mixtures and of the processes in which they take part. A principal feature of the treatment is the use of what may be called fundamental coordinates expressing directly the content of the three fundamental laws which must be strictly observed in the analysis of any physical process. The law of conservation of matter is expressed by whichever of the coordinates, mol-fraction, weight fraction, or weight ratio, is most convenient to the problem at hand; the law of conservation of energy is expressed by the coordinate, enthalpy, since most processes contemplated are of the steady-flow type in which the energy convected with the fluid is its enthalpy; the second law of thermodynamics is expressed by the coordinate entropy. The book makes extensive use of graphical methods; the diagrams are numerous and show obvious signs of care in their preparation.

The first chapter is devoted to the liquefaction of gases with particular reference to the Linde and Claude cycles both of which are based upon the well known Joule-Thomson-effect phenomena. The extent of inherent irreversibilities in these cycles is brought into prominence by application of the second law and the various methods of reducing them are discussed.

The second chapter is devoted to the properties of air-water mixtures, commonly referred to as moist air, and to an analysis of the important processes of evaporation and condensation occurring in such mixtures. The Mollier, i-x, diagram is used throughout; this diagram is constructed with those coordinates which most directly express the fundamental laws governing the processes involved. In the introduction of this chapter, the author states his opinion that any attempt to investigate the departures from Dalton's law in the case of moist air is not only superfluous, but would pretend to a degree of accuracy which is not real because, in the air actually encountered in practice, there are always present impurities which affect its properties to an unknown extent. This statement, it is believed, not only violates the spirit of thermodynamic consistency in evidence throughout most of the book, but actually underestimates the practical importance of these departures. It is also surprising that the author should pretend to derive the so-called Lewis law which has long been known to be incorrect in the general case and to owe its approximate correctness in the case of moist air to fortuitous circumstances.

In the third chapter, the general properties of binary mixtures, with and without phase differences, are discussed with particular reference to the Merkel diagram in which specific enthalpy and weight-fraction, (alternatively mol-fraction) are used as coordinates. The integral and differential heats of dilution and solution, also heats of evaporation and of fusion are clearly explained. The next chapter is devoted to typical processes in which binary mixtures take part, such as evaporation, sublimation, absorption, distillation, rectification and separation. These are two of the most valuable chapters of the book. There follow discussions of the problems of material transport between liquid and vapor, and a short development of the theory of the absorption refrigeration cycle.

Following a chapter devoted to the general thermodynamic relations and conditions for equilbrium, there appear chapters on combustion of liquid and solid fuels, production of gas from solid fuels, equilibrium under chemical reactions in gas mixtures, and finally on Nernst's third law of thermodynamics.

The book carries with it a pamphlet containing 74 problems with solutions; also a portfolio containing Mollier diagrams and entropy-concentration diagrams for moist air, ammonia-water, ethylalcohol-water, and nitrogen-oxygen mixtures. In view of the increasing importance of the subjects treated, the fortunate choice of coordinates in terms of which the treatment is worked out, and the care with which illustrations and diagrams are prepared, the book will be found to have immense value to student and engineer alike.

Analysis of Spherical Shells of Variable Wall Thickness[1]

By MERHYLE F. SPOTTS,[2] BALTIMORE, MD.

This article presents a solution to the problem of finding the forces and moments which occur in a spherical shell which is axisymmetrically loaded, when the variation in wall thickness is taken as a quadratic function of the coordinate of latitude.

The so-called Love-Meissner differential equations for the case of nonuniform wall thickness are derived herein. By appropriate substitutions these are reduced to one linear equation of the fourth order having constant coefficients. The solution to this equation when taken in the homogeneous form is first given. This homogeneous solution will be the general solution for all problems where the shell surface is free from external force, and the only loads on the shell consist of forces and moments applied at the boundaries.

When, however, the shell surface itself is loaded, a particular integral, which will depend upon the type of loading, must also be obtained for the nonhomogeneous equations.

The solution contained herein is illustrated by a numerical example for a shell of one boundary when acted upon by dead-load forces, and the results are plotted.

Historical

THE MODERN theory for shells having a wall thickness sufficiently great to resist bending may be said to date from Love (1)[3] who in 1892 gave the equilibrium equations for an element of the surface.

Differential equations for a spherical shell of constant wall thickness with axisymmetrical boundary loads were obtained by Reissner (2). These were solved by Blumenthal (3) by an asymptotic integration. Meissner (4) also obtained a solution in the form of a hypergeometric series.

Later Meissner (5) pointed out that the solution obtained for cylindrical shells could be applied to sufficiently thin spherical shells when the angle of opening is large. This is satisfactory in the region near the boundary since the stresses produced by bending are rapidly damped out. Geckeler (6) arrived at this same conclusion by taking the differential equations for a spherical shell and neglecting the terms of less importance.

In regard to the problem of shells of rotation of variable wall thickness, a solution has been presented by Meissner (7) for different variations in thickness and shape of meridian curve. An approximate solution for spherical shells of variable thickness has also been given by Geckeler (6).

Notation

a = radius of sphere
d = thickness of shell at pole or apex
D = $E\delta^3/12(1-\mu^2)$ modulus of flexural rigidity
E = Young's modulus
M_1 = unit bending moment with respect to φ
M_2 = unit bending moment with respect to θ
N_1 = unit meridional normal force
N_2 = unit hoop force
Q = unit meridional shearing force
r_0 = radius of latitude circle
v = meridional displacement
w = radial displacement
Y = unit external load parallel to meridian
Z = unit external load normal to surface
γ = weight per unit volume of shell
δ = thickness of shell
ϵ_1 = elongation along meridian
ϵ_2 = elongation along latitude circle
θ = coordinate of longitude
κ_1 = change of curvature with respect to φ
κ_2 = change of curvature with respect to θ
μ = Poisson's ratio
φ = coordinate, complement of latitude
χ = rotation of meridional tangent

Solution for the Case When the Shell Surface Is Free From External Forces

The usual elastic assumptions are made, namely, that the material is homogeneous, isotropic, and obeys Hooke's law, and that straight lines initially normal to the middle surface remain straight and normal to that surface after bending.

Fig. 1 shows an element cut from a sphere having a vertical axis, and a radius a. The coordinate φ of the element is measured from the axis in a downward direction, and the coordinate θ is measured from any fixed axial plane.

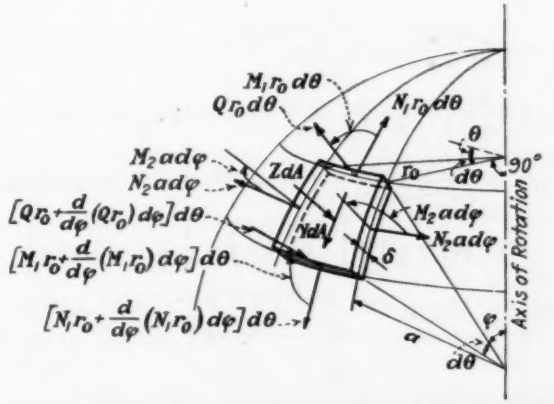

Fig. 1 Element of Spherical Surface With the Forces and Moments Which Produce Equilibrium

[1] Taken from a dissertation submitted in partial fulfillment of the requirements for the degree of Doctor of Philosophy in the University of Michigan.

[2] Instructor, Department of Mechanical Engineering, Johns Hopkins University.

[3] Numbers in parentheses refer to the Bibliography.

Presented at the National Meeting of the Applied Mechanics Division of The American Society of Mechanical Engineers, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1939, for publication at a later date.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

The top and bottom edges of the element are formed by two conical surfaces inclined to the axis by the angles φ and $\varphi + d\varphi$. The sides are formed by two meridional sections an angle $d\theta$ apart.

The quantities N_1, N_2, and Q represent force per unit length of edge; M_1 and M_2 represent moment per unit length; and Y and Z represent force per unit area. Positive directions are as shown in Fig. 1. The element, together with all forces, moments, and external loads, is symmetrical with respect to the axis. Thus no other forces or moments than those shown in Fig. 1 need be considered. All forces and moments are thus functions of the coordinate φ only.

As shown in the Appendix it is possible to write three equations of equilibrium for the element together with four more equations expressing relationships between the deformations. These seven equations make it possible to solve for the seven unknowns N_1, N_2, Q, M_1, M_2, v, and w, where v is the displacement of the element along a meridian, positive downward, and w is the displacement along the radius, positive outward.

If the variation in wall thickness is now taken as

$$\delta = d(1 + \alpha\varphi)^2 \quad \ldots\ldots [1]$$

where d is the thickness at the pole, and α is an arbitrarily chosen constant, and the same approximations are made as in the case of constant thickness (10), these equations may be reduced to one linear equation of the fourth order having constant coefficients.

The values of the unknowns,[4] when the equation is taken in the homogeneous form, are found to be[5,6]

$$^\circ Q = [d^{1/2}/(\sin\varphi)^{1/2}]\{C_1(1+\alpha\varphi)^{(3/2)+k}\cos[k\log(1+\alpha\varphi) - \gamma_1] + C_2(1+\alpha\varphi)^{(3/2)-k}\cos[k\log(1+\alpha\varphi) - \gamma_2]\} \quad \ldots\ldots [2]$$

$$^\circ Q' = \frac{C_1 d^{1/2}}{(\sin\varphi)^{1/2}}(1+\alpha\varphi)^{(1/2)+k}\left\{-\alpha k\sin[k\log(1+\alpha\varphi) - \gamma_1] + \left[\alpha\left(\frac{3}{2}+k\right) - \frac{1}{2}(1+\alpha\varphi)\cot\varphi\right]\cos[k\log(1+\alpha\varphi) - \gamma_1]\right\} + \frac{C_2 d^{1/2}}{(\sin\varphi)^{1/2}}(1+\alpha\varphi)^{(1/2)-k}\left\{-\alpha k\sin[k\log(1+\alpha\varphi) - \gamma_2] + \left[\alpha\left(\frac{3}{2}-k\right) - \frac{1}{2}(1+\alpha\varphi)\cot\varphi\right]\cos[k\log(1+\alpha\varphi) - \gamma_2]\right\} \quad \ldots\ldots [3]$$

$$^\circ\chi = \frac{2\alpha^2 k^2}{Ed^{1/2}(\sin\varphi)^{1/2}}\{C_1(1+\alpha\varphi)^{-(5/2)+k}\sin[k\log(1+\alpha\varphi) - \gamma_1] - C_2(1+\alpha\varphi)^{-(5/2)-k}\sin[k\log(1+\alpha\varphi) - \gamma_2]\} \quad \ldots\ldots [4]$$

$$^\circ\chi' = \frac{2\alpha^2 k^2 C_1}{Ed^{1/2}(\sin\varphi)^{1/2}}(1+\alpha\varphi)^{-(7/2)+k}\left\{\alpha k\cos[k\log(1+\alpha\varphi) - \gamma_1] + \left\{\alpha\left(-\frac{5}{2}+k\right) - \frac{1}{2}(1+\alpha\varphi)\cot\varphi\right\}\sin[k\log(1+\alpha\varphi) - \gamma_1]\right\} + \frac{2\alpha^2 k^2 C_2}{Ed^{1/2}(\sin\varphi)^{1/2}}(1+\alpha\varphi)^{-(7/2)-k}\left\{-\alpha k\cos[k\log(1+\alpha\varphi) - \gamma_2] + \left[\alpha\left(\frac{5}{2}+k\right) + \frac{1}{2}(1+\alpha\varphi)\cot\varphi\right]\sin[k\log(1+\alpha\varphi) - \gamma_2]\right\} \quad \ldots\ldots [5]$$

$$^\circ N_1 = -^\circ Q\cot\varphi \quad \ldots\ldots [6]$$

$$^\circ N_2 = -^\circ Q' \quad \ldots\ldots [7]$$

[4] The index $^\circ( )$ indicates the homogeneous solution.

[5] Certain minor terms have been omitted in these results.

[6] Differentiation with respect to φ is represented by the prime $( )'$.

$$^\circ M_1 = (D/a)(^\circ\chi' + \mu\,^\circ\chi\cot\varphi) \quad \ldots\ldots [8]$$

$$^\circ M_2 = (D/a)(^\circ\chi\cot\varphi + \mu\,^\circ\chi') \quad \ldots\ldots [9]$$

where C_1, C_2, γ_1, and γ_2, are constants of integration which must be determined from the loading and boundary conditions;

$$k = (1/\alpha)(a/d)^{1/2}[3(1-\mu^2)]^{1/4} \quad \ldots\ldots [10]$$

μ = Poisson's ratio

χ = rotation due to deformation of the meridional tangent, or the normal to the shell surface, taken positive clockwise

$$D = E\delta^3/[12(1-\mu^2)] \quad \ldots\ldots [11]$$

modulus of flexural rigidity, a variable because of the presence of δ.

It may be observed from the foregoing formulas that the pole ($\varphi = 0$), is a singular point, but its local character does not affect the accuracy of the results at other points.

This solution applies to the general case of the shell of two boundaries. Constants C_1 and γ_1 are determined from conditions which prevail on the lower boundary, and C_2 and γ_2 from conditions on the upper boundary.

When the shell is closed, that is, extends all the way to the pole, $C_2 = \gamma_2 = 0$ and only the constants C_1 and γ_1 must be evaluated. A proof may be given for this based on consideration of the fact that for the closed shell the shearing force Q and the rotation of the meridional tangent χ must both be zero at the pole.

Particular Solution When the Load Is Distributed Over the Surface of the Shell

The particular integral for the nonhomogeneous differential equations will of course depend upon the type of loading to which the shell surface is subjected.

In general it is not possible to obtain a particular integral to the lengthy nonhomogeneous equations by means of any of the recognized methods, and resort must be made to approximations.

For this purpose for most types of loading it is satisfactory to use the membrane forces as the particular solutions for N_1 and N_2, and take Q as equal to zero.

Example

The foregoing solution will now be applied to a numerical example.

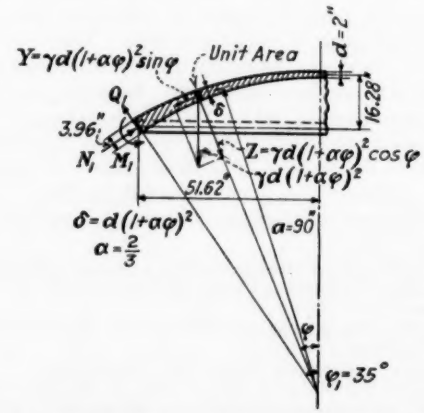

Fig. 2 Shell of Example Solved for Dead Load

Consider the closed shell of concrete with built-in boundary, as illustrated in Fig. 2, when the loading is taken as its own weight.

The numerical data for this shell are: $a = 90$ in. radius:

$\varphi_1 = 35$ deg, angle of opening; $d = 2$ in., thickness at pole; $\alpha = 2/3$; $E = 3{,}000{,}000$ psi; $\mu = 0.15$; $\gamma = 0.0868$ lb per cu in., weight; and from Equation [10], $k = 13.1676$.

Calculation of Constants of Integration

As shown in Fig. 2, the tangential and normal components of the surface load are

$$Y = \gamma d(1 + \alpha\varphi)^2 \sin \varphi \quad [12]$$

$$Z = \gamma d(1 + \alpha\varphi)^2 \cos \varphi \quad [13]$$

For a fixed-edge shell the conditions to be satisfied on the boundary are

$$v = 0, \quad w = 0, \quad \text{and} \quad \chi = 0 \quad [14][15][16]$$

As shown in the Appendix, the expression for w is

$$w = (a/E\delta)(N_2 - \mu N_1) - v \cot \varphi \quad [75]$$

This will be satisfied on the boundary where both v and w are zero if

$$N_2 - \mu N_1 = 0 \quad [17]$$

Since N_1 and N_2 denote the general solution for these forces this equation may be written

$$^{\circ}N_2 + {}^{DL}N_2 - \mu(^{\circ}N_1 + {}^{DL}N_1) = 0 \quad [18]$$

or

$$^{\circ}N_2 + {}^{m}N_2 - \mu(^{\circ}N_1 + {}^{m}N_1) = 0 \quad [19]$$

where the index $^{DL}(\ )$ indicates particular solution for dead load, and $^{m}(\ )$ indicates the membrane force.

Substituting the known expressions for the membrane forces for a sphere, and the values of the homogeneous solution from Equations [6] and [7] yields

$$-{}^{\circ}Q' + \frac{F(\varphi)}{\sin^2 \varphi} - Za - \mu\left[-{}^{\circ}Q \cot \varphi - \frac{F(\varphi)}{\sin^2 \varphi}\right] = 0 \quad [20]$$

where

$$F(\varphi) = a \int_0^{\varphi} (Y \sin \varphi + Z \cos \varphi) \sin \varphi d\varphi \quad [21]$$

For dead load as given by Equations [12] and [13] this becomes

$$F(\varphi) = a\gamma d[2a(1 + \alpha\varphi) \sin \varphi - (1 + \alpha\varphi)^2 \cos \varphi + 2a^2 \cos \varphi + 1 - 2a^2] \quad [22]$$

For the calculation of the constants, it will be convenient to let

$$\gamma_1 = k \log (1 + \alpha\varphi_1) + \psi_1 \quad [23]$$

where φ_1 is the angle of opening of the shell and ψ_1 is another constant.

Substituting for $^{\circ}Q$ and $^{\circ}Q'$ in Equation [20] and performing the numerical computations for $\varphi = \varphi_1 = 35$ deg gives

$$C_1(\sin \psi_1 + 0.96510 \cos \psi_1) = -0.00534 \quad [24]$$

Equation [16] may be written as

$$^{\circ}\chi + {}^{DL}\chi = 0 \quad [25]$$

In Equation [54] as derived in the Appendix the value of $^{DL}\chi$, if the particular solution for Q is neglected, is found to be

$$E\,{}^{DL}\chi = (1/\delta)\Phi(\varphi) \quad [26]$$

where $\Phi(\varphi)$ as given by Equation [55] becomes for dead load

$$\Phi(\varphi) = -(1 + \mu)\frac{\delta'}{\delta}\frac{F(\varphi)}{\sin^2 \varphi} + a\gamma d(2 + \mu)(1 + \alpha\varphi)^2 \sin \varphi \quad [27]$$

Substituting Equations [4] and [26] in [25] and performing the numerical work for $\varphi = \varphi_1 = 35$ deg yields

$$C_1 \sin \psi_1 = 0.001054 \quad [28]$$

Solving Equations [24] and [28] gives

$$C_1 = -0.006707 \quad [29]$$

$$\psi_1 = -(9°2'32'') = -0.15782 \text{ radians} \quad [30]$$

from which

$$\gamma_1 = 4.34067 \quad [30a]$$

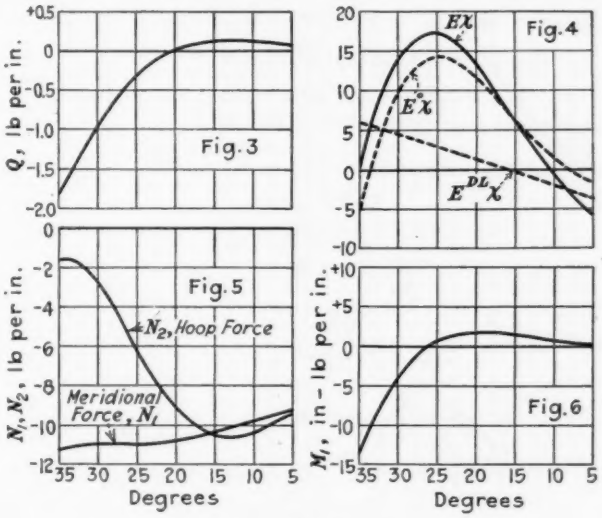

FIG. 3 SHEARING FORCE Q

FIG. 4 ROTATION OF MERIDIONAL TANGENT

FIG. 5 HOOP FORCE N_2

FIG. 6 MERIDIONAL BENDING MOMENT M_1

When the constants C_1 and γ_1 are determined, the solution as represented by Figs. 3, 4, 5, and 6 may be completed by substitution in the appropriate equations.

In computing the values of the bending moments it is necessary to have $^{DL}\chi'$. Much labor will be saved if, instead of differentiating Equation [26], the curve for $E\,{}^{DL}\chi$ as shown in Fig. 4 is first represented by an empirical polynomial of the second degree and then differentiated.

Appendix

(*a*) *Equilibrium Equations*

The equations of equilibrium of the element shown in Fig. 1 are

$$(Q \sin \varphi)' + N_1 \sin \varphi + N_2 \sin \varphi + Za \sin \varphi = 0 \quad [31]$$

$$(N_1 \sin \varphi)' - N_2 \cos \varphi - Q \sin \varphi + Ya \sin \varphi = 0 \quad [32]$$

$$(M_1 \sin \varphi)' - M_2 \cos \varphi - Qa \sin \varphi = 0 \quad [33]$$

Expressions for N_1 and N_2 may be obtained as follows: Multiply Equation [31] by cos φ and Equation [32] by sin φ and add.

$$(N_1 \sin \varphi)' \sin \varphi + N_1 \sin \varphi \cos \varphi + (Q \sin \varphi)' \cos \varphi - Q \sin^2 \varphi + a(Y \sin \varphi + Z \cos \varphi) \sin \varphi = 0$$

Integrating this equation gives

$$(N_1 \sin \varphi + Q \cos \varphi) \sin \varphi + F(\varphi) = 0 \quad \ldots\ldots [34]$$

where $F(\varphi)$ is as given by Equation [21].

From Equations [34] and [31] is obtained

$$N_1 = -Q \cot \varphi - F(\varphi)/\sin^2 \varphi \quad \ldots\ldots [35]$$

$$N_2 = -Q' + [F(\varphi)/\sin^2 \varphi] - Za \quad \ldots\ldots [36]$$

Equations [35] and [36] become Equations [6] and [7], respectively, when taken in the homogeneous form. On the other hand if the shell is a membrane and incapable of resisting shear and moment, the membrane forces N_1 and N_2 may be obtained from Equations [35] and [36] by setting Q and Q' equal to zero.

(*b*) *Relationships Involving Deformations*

Fig. 7*a* shows a vertical section through the element of Fig. 1 before and after deformation of the shell.

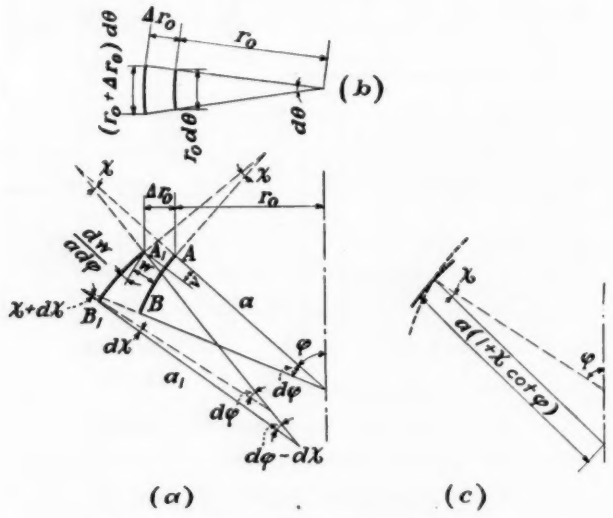

FIG. 7 DEFORMATION OF THE ELEMENT

[(*a*) Rotation of meridional tangent, also radius of curvature in direction of coordinate φ; (*b*) view of upper edge of element; (*c*) radius of curvature in direction of coordinate θ.]

A point originally at A on the upper edge of the element moves to A_1 undergoing the two displacements v and w.

Point B on the lower edge of the shell moves to B_1 after receiving displacements of $v + v'd\varphi$ and $w + w'd\varphi$.

The tangent to the meridian drawn at A has thus rotated counterclockwise through an angle v/a due to v, and clockwise through an angle w'/a because of the variation in w. The total rotation is thus

$$\chi = (w' - v)/a \quad \ldots\ldots [37]$$

It will be convenient to use χ as one of the unknowns rather than v and w separately.

Consider the curvature of the normal section of the surface whose plane contains the tangent to the meridian curve.

Normals drawn from the points B and B_1, Fig. 7*a*, will intersect at an angle $\chi + d\chi$. Normals from the points A_1 and B_1 will then intersect at an angle $d\varphi - d\chi$. The length of the arc AB then is

$$ad\varphi = a_1 (d\varphi - d\chi)$$

if a_1 be the radius of curvature after deformation, and if any change in length between AB and A_1B_1 be neglected.

The curvature for the deformed element then is

$$1/a_1 = (1/a)(1 - \chi')$$

and the change of curvature in the φ-direction is

$$\kappa_1 = \chi'/a = (w' - v)'/a^2 \quad \ldots\ldots [38]$$

Now consider the curvature of the section at right angles to φ-direction. Neglect the slight displacement of the element and regard only the effect of the rotation. The new radius of curvature extends from the element to the axis of the sphere, and as shown in Fig. 7*c*, has a length approximately equal to $a(1 + \chi \cot \varphi)$.

The change of curvature in the θ-direction is then found to be approximately

$$\kappa_2 = (\chi \cot \varphi)/a = [(w' - v)/a^2] \cot \varphi \quad \ldots\ldots [39]$$

Thus for the bending moments

$$M_1 = D(\kappa_1 + \mu\kappa_2) = (D/a)(\chi' + \mu\chi \cot \varphi)$$
$$= (D/a^2)[(w' - v)' + \mu(w' - v) \cot \varphi] \quad \ldots\ldots [40]$$

$$M_2 = D(\kappa_2 + \mu\kappa_1) = (D/a)(\chi \cot \varphi + \mu\chi')$$
$$= (D/a^2)[(w' - v) \cot \varphi + \mu(w' - v)'] \quad \ldots\ldots [41]$$

As shown in Fig. 7*a* the length of the arc A_1B_1 is given approximately by $(ad\varphi + v'd\varphi)[(a + w)/a]$. Neglecting terms of higher order the increase in the length of the element then is $(v' + w)d\varphi$ and the deformation is

$$\epsilon_1 = (v' + w)/a \quad \ldots\ldots [42]$$

In the θ-direction the new length of arc as shown in Fig. 7*b* is $(r_0 + \Delta r_0)d\theta$. The increase in length then is

$$\Delta r_0 d\theta = (v \cos \varphi + w \sin \varphi)d\theta$$

and the elongation is

$$\epsilon_2 = (1/a)(v \cot \varphi + w) \quad \ldots\ldots [43]$$

The edge forces are thus seen to be

$$N_1 = [E\delta/(1 - \mu^2)](\epsilon_1 + \mu\epsilon_2)$$
$$= [E\delta/a(1 - \mu^2)][v' + w + \mu(v \cot \varphi + w)] \quad \ldots\ldots [44]$$

$$N_2 = [E\delta/(1 - \mu^2)](\epsilon_2 + \mu\epsilon_1)$$
$$= [E\delta/a(1 - \mu^2)][v \cot \varphi + w + \mu(v' + w)] \quad \ldots\ldots [45]$$

The seven Equations [31], [32], [33], [40], [41], [44], and [45] make it possible to solve for the seven aforementioned unknowns contained therein. These equations will first be reduced to two equations in the unknowns Q and χ.

(*c*) *Differential Equations of the Shell*

Substituting Equations [40] and [41] into Equation [33] gives the first differential equation of the shell.

$$\chi'' + \chi'[\cot \varphi + 3(\delta'/\delta)] - \chi[\cot^2 \varphi + \mu - 3\mu(\delta'/\delta) \cot \varphi] = a^2Q/D \quad \ldots\ldots [46]$$

For the second equation proceed as follows. Combine Equations [35] and [36] as here indicated

$$N_2 - \mu N_1 = -Q' + \mu Q \cot \varphi + (1 + \mu)\frac{F(\varphi)}{\sin^2 \varphi} - Za \quad \ldots [47]$$

$$N_2' - \mu N_1' = -Q'' + \mu Q' \cot \varphi - \mu Q \csc^2 \varphi + \frac{1 + \mu}{\sin^2 \varphi} F'(\varphi) - \frac{2(1 + \mu) \cos \varphi F(\varphi)}{\sin^3 \varphi} - Z'a \quad \ldots [48]$$

$$N_1 - N_2 = Q' - Q \cot \varphi - \frac{2F(\varphi)}{\sin^2 \varphi} + Za \quad \ldots\ldots [49]$$

Combine Equations [44] and [45]

$$v' + w = (a/E\delta)(N_1 - \mu N_2) \quad [50]$$

$$v \cot \varphi + w = (a/E\delta)(N_2 - \mu N_1) \quad [51]$$

Subtract Equation [51] from [50]

$$v' - v \cot \varphi = (a/E\delta)(1 + \mu)(N_1 - N_2) \quad [52]$$

Differentiating Equation [51] and subtracting the product of Equation [52] times cot φ gives

$$w' - v = (a/E\delta)[-(\delta'/\delta)(N_2 - \mu N_1) + (N_2' - \mu N_1') - (1 + \mu)(N_1 - N_2)\cot\varphi] \quad [53]$$

Substituting Equations [47], [48], [49], and [37] into Equation [53] gives the second differential equation of the shell.

$$Q'' + Q'[\cot\varphi - (\delta'/\delta)] - Q[\cot^2\varphi - \mu - \mu(\delta'/\delta)\cot\varphi] = -E\delta\chi - (1+\mu)\frac{\delta'}{\delta}\frac{F(\varphi)}{\sin^2\varphi} + a[(1+\mu)Y + \frac{\delta'}{\delta}Z - Z'] = -E\delta\chi + \Phi(\varphi) \quad [54]$$

where

$$\Phi(\varphi) = -(1+\mu)\frac{\delta'}{\delta}\frac{F(\varphi)}{\sin^2\varphi} + a[(1+\mu)Y + \frac{\delta'}{\delta}Z - Z'] \quad [55]$$

Equations [46] and [54] are general, and will apply to any type of variation in δ, and to any type of external load.

(d) Solution of the Homogeneous Equations

Equation [46] is homogeneous in the variables χ and Q, and Equation [54] may be made thus by omitting the term $\Phi(\varphi)$ which involves the components Y and Z of the external load.

An approximate solution may be obtained to Equations [46] and [54] based on the assumption that the expressions which represent χ and Q are of such a type that the first two terms on the left of Equations [46] and [54] are of much more importance than the third term, and that this third term may therefore be neglected.

Equation [46] becomes then when the term in χ is omitted

$$\chi'' + \chi'[\cot\varphi + 3(\delta'/\delta)] = a^2Q/D \quad [56]$$

The term in χ' may be removed from this equation by the following substitution giving an equation in the new variable $\bar{\chi}$. Let

$$\chi = \bar{\chi}e^{-1/2\int(\cot\varphi + 3\delta'/\delta)d\varphi} = \bar{\chi}/(\delta^3\sin\varphi)^{1/2} \quad [57]$$

Substitute in Equation [56] and neglect terms in the variable itself.

$$\bar{\chi}''/(\delta^3\sin\varphi)^{1/2} = a^2Q/D \quad [58]$$

Omitting the term in Q, Equation [54] becomes

$$Q'' + Q'[\cot\varphi - (\delta'/\delta)] = -E\delta\chi \quad [59]$$

The term in Q' is removed by the substitution

$$Q = \bar{Q}e^{-1/2\int(\cot\varphi - \delta'/\delta)d\varphi} = \bar{Q}(\delta/\sin\varphi)^{1/2} \quad [60]$$

Substituting in Equation [59] and neglecting terms in the variable itself gives

$$\bar{Q}''(\delta/\sin\varphi)^{1/2} = -E\delta\chi \quad [61]$$

Equation [60] should now be substituted into [58] and Equation [57] into [61].

$$\bar{\chi}''\delta = [12a^2(1-\mu^2)/E]\bar{Q} \quad [62]$$

$$\bar{Q}''\delta = -E\bar{\chi} \quad [63]$$

Eliminating $\bar{\chi}$ between Equations [62] and [63] gives

$$\delta^2\bar{Q}^{IV} + 2\delta\delta'\bar{Q}''' + \delta\delta''\bar{Q}'' + 12a^2(1-\mu^2)\bar{Q} = 0 \quad [64]$$

Substituting the value of δ as given by Equation [1] gives

$$(1+\alpha\varphi)^4\bar{Q}^{IV} + 4\alpha(1+\alpha\varphi)^3\bar{Q}''' + 2\alpha^2(1+\alpha\varphi)^2\bar{Q}'' + 12(a^2/d^2)(1-\mu^2)\bar{Q} = 0 \quad [65]$$

This equation is reduced to one with constant coefficients by the following substitutions. Let

$$u = 1 + \alpha\varphi \quad [66]$$

$$u^4\frac{d^4\bar{Q}}{du^4} + 4u^3\frac{d^3\bar{Q}}{du^3} + 2u^2\frac{d^2\bar{Q}}{du^2} + 4k^4\bar{Q} = 0 \quad [67]$$

where k is given by Equation [10]. Now let

$$u = e^t \quad [68]$$

$$\frac{d^4\bar{Q}}{dt^4} - 2\frac{d^3\bar{Q}}{dt^3} + \frac{d^2\bar{Q}}{dt^2} + 4k^4\bar{Q} = 0 \quad [69]$$

The corresponding characteristic equation has roots of

$$m = (1/2)[1 \pm (1 \pm 8ik^2)^{1/2}] \quad [70]$$

but since $1 \ll 8k^2$ the term unity under the radical will be neglected giving values of m of

$$m = (1/2) \pm (1 \pm i)k \quad [71]$$

The homogeneous value of the shearing force is thus found to be

$$\begin{aligned} {}^cQ &= \frac{d^{1/2}(1+\alpha\varphi)}{(\sin\varphi)^{1/2}}\{A_1e^{[1/2+(1+i)k]t} + A_2e^{[1/2+(1-i)k]t} + A_3e^{[1/2-(1-i)k]t} + A_4e^{[1/2-(1+i)k]t}\} \\ &= \frac{d^{1/2}(1+\alpha\varphi)}{(\sin\varphi)^{1/2}}\{e^{(1/2+k)t}(A_5\cos kt + A_6\sin kt) + e^{(1/2-k)t}(A_7\cos kt + A_8\sin kt)\} \\ &= \frac{d^{1/2}(1+\alpha\varphi)}{(\sin\varphi)^{1/2}}[C_1e^{(1/2+k)t}\cos(kt-\gamma_1) + C_2e^{(1/2-k)t}\cos(kt-\gamma_2)] \end{aligned} \quad [72]$$

Upon substitution of $t = \log(1+\alpha\varphi)$ the value for the shearing force as given by Equation [2] is obtained. The rotation of the meridional tangent χ may be obtained by substitution into Equations [60] and [61].

Combining Equations [42] and [43] gives

$$v' - v\cot\varphi = a(\epsilon_1 - \epsilon_2) \quad [73]$$

The integral of this is

$$v = C\sin\varphi + a\sin\varphi\int\frac{\epsilon_1 - \epsilon_2}{\sin\varphi}d\varphi \quad [74]$$

where C is the constant of integration.

Substituting Equations [44] and [45] into Equation [43] yields

$$w = (a/E\delta)(N_2 - \mu N_1) - v\cot\varphi \quad [75]$$

Summary

An approximate method of treating spherical shells of variable thickness, similar to that developed for spherical shells of constant thickness (10), is developed in this paper.

It has been shown by Hetényi (10) that the method of approximation as used here for shells of variable thickness will, when applied to the case of constant wall thickness, give results which

are almost identical with those given by the exact solution of the differential equations. Very likely this same relative accuracy will hold when the wall thickness varies. In all cases substitution in the differential equations constitutes the final criterion.

The Spring Clutch

By C. F. WIEBUSCH,[1] NEW YORK, N. Y.

The mathematical theory is developed for the spring clutch which consists of two coaxial cylinders placed end to end and coupled torsionally by a coil spring fitted over them. Relations are derived whereby it is possible to design spring clutches in terms of the requirements and the constants of the spring material. Experimental verification of the relations is given. The theory of residual and active stresses as applied to the springs is discussed.

THE TYPE of spring clutch to be discussed here consists of two cylinders placed end to end, rotating on a common axis, and torsionally coupled by the friction between the cylinders and a coil spring fitted over the cylinders. Such clutches have been extensively used on telephone-dial governors to permit the dial to be wound up without dragging the governor and to couple the governor to the system with a negligible backlash for motion in the pulsing direction. A photograph of such a clutch, assembled and apart, from a telephone dial is shown in Fig. 1. In spite of widespread use there seems to be little theoretical discussion of this device in the literature.

It is obvious that if the driving drum be rotated in the direction to wind up the spring and decrease the diameter, the spring will grip the cylinders and will be capable of exerting more torque than it would in the direction of rotation which tends to unwind the spring. Equations are to be developed which will permit the calculation of these two torque values in terms of the physical dimensions and the material constants of the clutch.

Torque of Spring Clutch in the Free Direction

In Fig. 2 assume that the spring is fastened to the left-hand arbor in order that any slipping which may take place must occur on the driving drum on the right. Assume also that the spring is so formed that the inward radial force on the drum per unit length of the material is constant when no torque is applied.

Notation

- l = length along the line of contact of the spring on the arbor, measured from the free end to any point, in.
- μ = coefficient of friction between the spring and the arbor
- r_2 = radius of the arbor, in.
- R_2 = radius to the neutral bending axis of the spring when on the arbor, in.
- N = number of turns on the right-hand arbor
- P = compression in the spring wire at any point due to the applied torque; this is not the stress in the material but the resultant force acting across the entire cross section of the wire, lb
- f_0 = radial force of spring on arbor when no torque is applied, lb per in. of contact line.

As compression exists in the spring wire at any point when the arbor is turned to make the spring unwind, there will be a radial force subtracting from f_0 at every point. This subtracting force is P/r_2. The increase of compression in the wire along the length of the line of contact due to friction is

$$dP = \mu(f_0 - P/r_2)dl \quad [1]$$

which upon integration gives

$$l = -(r_2/\mu) \ln [f_0 - (P/r_2)]C$$

where C is a constant of integration equal to $1/f_0$ since $P = 0$ at $l = 0$. Hence

$$P = r_2 f_0(1 - e^{-\mu l/r_2}) \quad [2]$$

Since $l = 2\pi r_2 N$, $P = r_2 f_0(1 - e^{-2\pi N\mu})$ [3]

Since the torque is equal to Pr_2

$$T = r_2^2 f_0(1 - e^{-2\pi N\mu}) \text{ (in-lb)} \quad [4]$$

It will be observed that for any but fractional values of $N\mu$ the exponential term becomes very small and

$$T = r_2^2 f_0 \qquad (N\mu > 1) \quad [5]$$

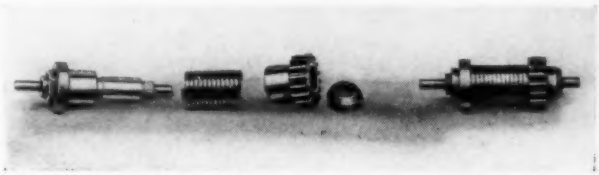

Fig. 1 Telephone-Dial Clutch

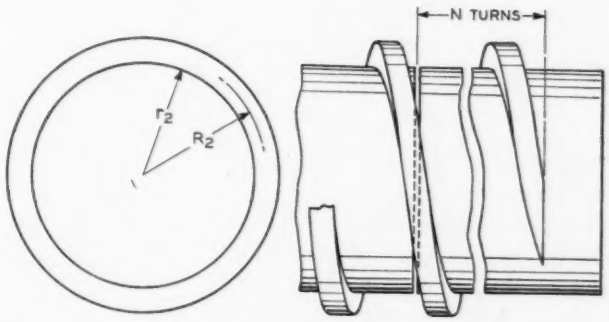

Fig. 2 Diagram of Spring Clutch

If $N\mu = 1.0$ this expression is in error by only 0.2 per cent. It can thus be seen that provided only that $N\mu$ does not become too small, variations in N or μ do not affect the torque exerted. The torque will depend only on the radius of the arbor and on the force f_0 which is controlled entirely by the dimensions and the elastic properties of the spring.

Torque of Spring Clutch in the Gripping Direction

If the torque is applied to the clutch in the direction to wind up the spring, instead of unwind it as in the previous case, the force P'/r_2 due to the tension P' in the spring wire adds to the inward force f_0 and the relation corresponding to Equation [1] is

$$dP' = \mu(f_0 + P'/r_2)dl \quad [6]$$

[1] Member of the technical staff of the Bell Telephone Laboratories, Inc.

Presented at the National Meeting of the Applied Mechanics Division of The American Society of Mechanical Engineers, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1939, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

From which by the same method as before

$$P' = r_2 f_0(e^{2\pi N\mu} - 1) \quad [7]$$

The corresponding torque is

$$T' = r_2^2 f_0(e^{2\pi N\mu} - 1) \text{ (in-lb)} \quad [8]$$

In this case the torque increases rapidly with an increase in either N or μ especially for large values of $N\mu$. The coefficient of friction is in general a rather variable factor. It is to be expected that the slipping torque will also be variable, but since a lower limit can in general be set for this coefficient it will always be possible to make the number of turns of the spring such as to give any desired lower limit of torque.

The Radial Force on the Arbor

One method of evaluating the force f_0 occurring in the torque relations depends on equating the potential energy of strain per unit length of the wire when on the arbor to the work done in expanding the spring from its free diameter to the diameter of the arbor.

Let

E = Young's modulus for the spring material, psi
I = the area moment of the wire section, in.^{4}
h = the radial thickness of the wire, in.
R_1 = free radius to the neutral axis, in.
r_1 = free inner radius of the spring, in.

Consider the portion of spring wire shown in Fig. 3 straightened out from the initial radius of curvature R_1 to the radius R_2. The

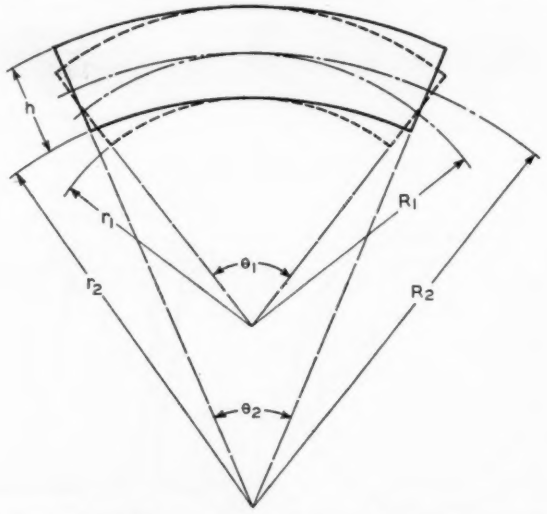

Fig. 3 Element of Spring in Initial and Expanded Condition

fibers above the neutral axis will be compressed while those below the neutral axis will be stretched. Let y be the distance of any given fiber from the neutral axis. The length of the undistorted fiber will be $L = (R_1 + y)\theta_1$ while after bending this same fiber will have the length $L' = (R_2 + y)\theta_2$. The strain or the change in length per unit length is

$$\frac{L - L'}{L} = 1 - \frac{(R_2 + y)\theta_2}{(R_1 + y)\theta_1} \quad [9]$$

Since along the neutral axis there is no change in length, $\theta_2 = L_0/R_2$ and $\theta_1 = L_0/R_1$. Substituting these values in Equation [9] gives

$$\text{Strain} = (y/R_2)\,(R_2 - R_1)/(R_1 + y) \quad [10]$$

The potential energy per unit volume in a material strained in tension or compression is

$$W/V = (E/2)(\text{Strain})^2 \quad [11]$$

Substituting the value of strain from Equation [10] in Equation [11] the energy density at any point of the deflected wire will be

$$\frac{W}{V} = \frac{E}{2}\left[\frac{y(R_2 - R_1)}{R_2(R_1 + y)}\right]^2 \quad [12]$$

Let b represent the width of the wire at the point y. Then for a wire symmetrical about the neutral axis the strain energy per unit length of the wire becomes

$$\frac{W}{l} = \int_{-h/2}^{h/2} \frac{E}{2}\left[\frac{y(R_2 - R_1)}{R_2(R_1 + y)}\right]^2 \frac{R_1 + y}{R_1}\, b\,dy \quad [13]$$

where the factor $(R_1 + y)/R_1$ represents the ratio of the length of the fiber at the point y to the length along the neutral axis. If all values of y, and hence also $h/2$, are small compared to R_1 there will be little error made in neglecting the y, which carries both positive and negative values, in the expression $R_1 + y$. Hence

$$\frac{W}{l} = \int_{-h/2}^{h/2} \frac{E}{2}\left(\frac{R_2 - R_1}{R_2 R_1}\right)^2 by^2 dy \quad [14]$$

The integral of by^2dy is the area moment I of the section and therefore

$$\frac{W}{l} = \frac{1}{2} EI \left(\frac{R_2 - R_1}{R_2 R_1}\right)^2 \quad [15]$$

This must be equal to the work done per unit length of the neutral axis, by the force per unit length $F(\Delta R)$ working through the distance ΔR where $\Delta R = R_2 - R_1$. That is

$$\int_0^{\Delta R} F(\Delta R)\, d\Delta R = \frac{1}{2} EI \left[\frac{\Delta R}{R_1(R_1 + \Delta R)}\right]^2 \quad [16]$$

Differentiating both sides with respect to ΔR gives $F(\Delta R)$ for the left-hand side, and after simplification

$$F(\Delta R) = \frac{EI}{R_1} \frac{\Delta R}{(R_1 + \Delta R)^3} \quad [17]$$

Substituting for ΔR its value $R_2 - R_1$ gives

$$F(\Delta R) = EI(R_2 - R_1)/R_1 R_2^3 \quad [18]$$

The equivalent force per unit length measured along the surface of the arbor must be larger than this value in the ratio of R_2/r_2 since the same total force is here distributed over a shorter length. This latter force is f_0, hence

$$f_0 = \frac{R_2}{r_2} F(\Delta R) = EI \frac{R_2 - R_1}{R_1 r_2 R_2^2} \text{ lb per in} \quad [19]$$

The value of f_0 calculated from this equation in terms of the constants of the spring material and the dimensions of the spring may be used in Equations [4] and [8] to calculate the free torque and the slipping torque of the clutch.

Experimental Check of the Free-Torque Relation

In order to check the validity of the relation for the free torque, Equation [4], and that for the radial force on the arbor, Equation [19], the free torque of a given spring on arbors of various diameters as well as the torque for different numbers of turns on the same arbor was measured. The spring of 0.0085 × 0.022-in. phosphor-bronze ribbon was attached to a short vertical shaft

suspended by a torsion fiber of measured torsional stiffness. The free end of the spring was placed over a vertical arbor capable of rotation. The arbor was rotated and the angle of twist of the torsion fiber was measured thus giving a measure of the slipping torque. The precision of the measurements of torque was about 0.5 per cent although the sensitivity to small changes was about 0.2 per cent. No measurable increase of torque occurred by increasing the number of turns on the arbor beyond six. This is to be expected if the coefficient of friction exceeds about 0.12.

For all succeeding measurements seven to eight turns were used. As a further check on the independence of the torque and the coefficient of friction for this number of turns a measurement was made before and after oiling the arbor and spring with a light lubricating oil. There was a decrease in torque of approximately 0.25 per cent.

The inside diameter of the spring as measured by a taper gage was 0.180 in. ± 0.001 in. The torque for arbors ranging in size from 0.182 to 0.193 in. was determined and is shown in Fig. 4. This curve extrapolated to zero torque gives, for an accurate measure of the inside diameter of the spring, 0.1794 in. Using this value and the quantity EI, determined by obtaining the resonant frequency of a straight short length of the ribbon, of which the spring was made, vibrating as a fixed free reed the radial force on the arbor as calculated by Equation [19] is shown by the dotted curve as a function of the arbor diameter $2r_2$. The points indicate values of f_0 obtained from the measured values of torque by the use of Equation [5]. The two sets of values agree within about 2 per cent.

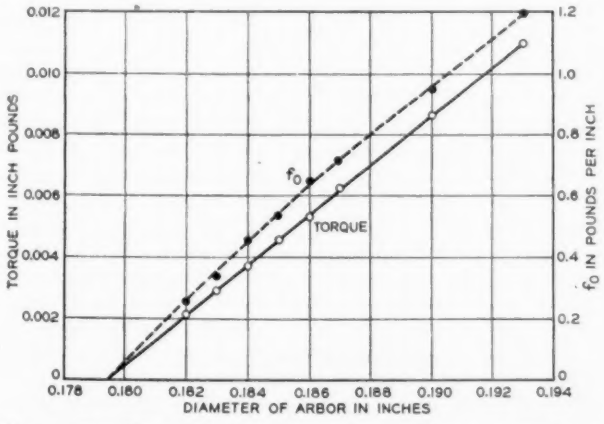

Fig. 4 The Free Torque and the Radial Force on the Arbor for a Phosphor-Bronze Spring on Arbors of Different Diameters

As a further check on the validity of the calculations under practical conditions, the free torque of a phosphor-bronze spring on a dial-governor arbor was measured for various numbers of turns of the spring engaging on the slipping arbor. The torque due to bearing friction alone with no spring in place was also measured and found to be approximately 0.001 in-lb. This constant value was subtracted from the other measured values of torque. The resulting values of free spring torque are plotted as a function of the number of turns in Fig. 5. The torque values calculated by Equations [4] and [19] and using the value of $\mu = 0.165$ obtained as described in the next section, are shown on the curve to indicate the agreement.

Experimental Check of the Holding-Torque Relation

It is to be expected that any relation for which the coefficient of friction is a controlling factor will be difficult to check accurately. Equation [8] for the slipping torque is of this type. It is possible however by taking a large number of measurements to establish the validity of the equation and then by determining limiting values for the coefficient of friction, to use this equation as a design relation, especially if only a minimum torque limit is set. Measurements of the slipping torque, as a function of the number of turns, were made on the same dial clutch that was used for checking the free torque.

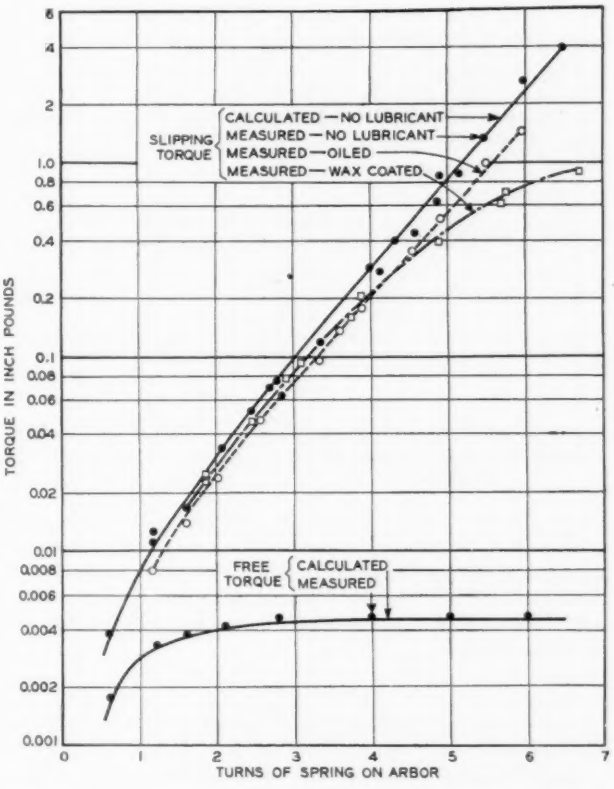

Fig. 5 Dependence of Torque on the Number of Turns of the Spring Engaging the Arbor

This slipping torque was not steady as was the case in the free direction but varied as much as ±20 per cent. An average value was taken in each case. An uncertainty also existed regarding the number of turns engaging the rotating arbor. Since the crossover from one arbor to the other requires practically one whole turn, slight differences in the arbor diameters may result in a gain or loss of almost half a turn. In addition to these factors there was an end effect due to the fact that the free end of the spring wire was cut off square rather than beveled but this factor although calculable was neglected in view of the other uncertainties. The results of these measurements are shown in Fig. 5.

From Equation [8] it can be seen that for large values of N the plot of T' versus N will be a straight line provided μ is independent of the force between the spring and the arbor. The slope of this straight line when multiplied by the proper constant, which can be shown to be 0.368, gives the coefficient of friction. For the experimental points shown in Fig. 5 this value of μ is 0.165. Using this value of μ in Equation [6] the calculated curve was plotted. Considering the uncertainties involved the calculated and measured curves are in good agreement.

The dotted curve of Fig. 5 shows the effect of lubricating the clutch with a light machine oil. This resulted in only a small

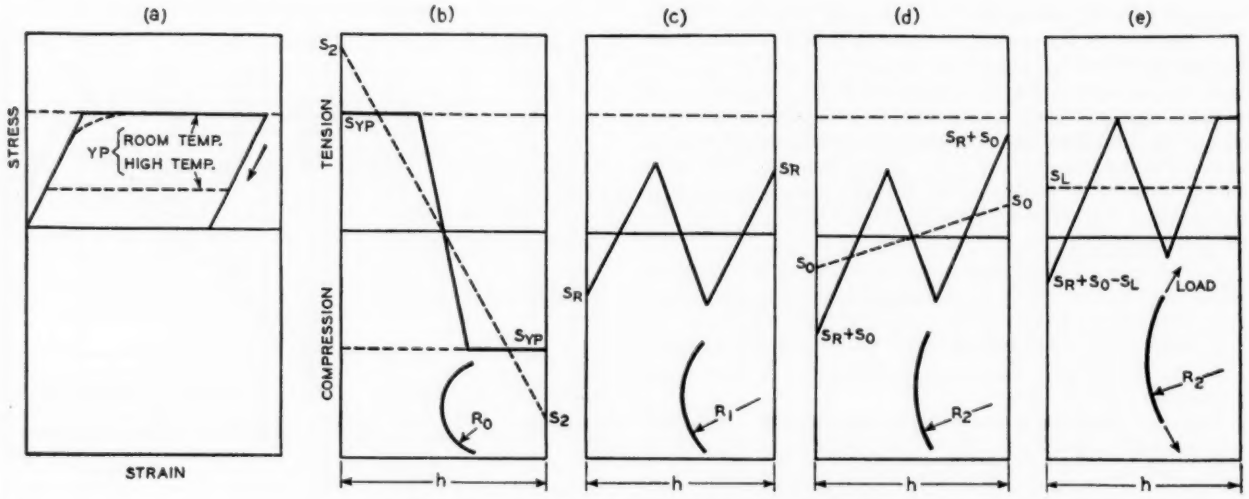

FIG. 6 IDEALIZED STRESS CONDITIONS IN CLUTCH SPRINGS

decrease of the coefficient of friction. The curve shown by the dashes illustrates the effect of lubricating a clutch with spermaceti. The coefficient was no longer a constant but decreased with an increase in load.

SPRING STRESSES

In determining the load that a spring clutch will withstand, first without stretching which will result in backlash, and second without breaking, initial as well as load stresses must be considered. The initial stresses are made up of the residual stresses due to forming the spring, plus the stresses due to expanding the spring to fit the arbor, that is from an inner radius r_1 to an inner radius r_2.

Of these limiting load values the easiest to calculate is the torque required to break the spring. This is given by the product of the radius of the spring and the breaking strength of the spring wire. Loads much smaller than this value would stretch some of the fibers of the spring, especially those in which a high initial stress already existed. As will be shown, such stretching will cause the radius to increase at those portions of the spring where the applied stresses are highest, that is, for those turns near the dividing line of the arbor.

Substituting for y, in Equation [10], the distances from the neutral axis to the extreme inner and outer fibers will give the strain in these fibers. Provided R_1 is considerably larger than $h/2$, half the thickness of the material, the distances to these extreme fibers becomes $h/2$ and the y in the denominator can be neglected in comparison to R_1. The maximum fiber stress due to placing the spring on the arbor is this value of strain multiplied by Young's modulus. Then

$$S_0 = \frac{h}{2R_2}\,\frac{R_2 - R_1}{R_1}E \qquad [20]$$

This stress is in the form of compression for the outer fibers and tension for the inner. Since a load on the clutch results in a tension in the spring, the stress given by Equation [20] must be added to the load tension stress to get the total stress on the inner fibers of the spring. This initial stress therefore reduces the load-carrying capacity of the clutch.

RESIDUAL SPRING STRESSES

When a straight wire is wound upon an arbor to form a coil spring the strain on the inner and outer fibers must exceed that corresponding to the yield-point and plastic-flow results. To simplify the discussion assume the idealized stress-strain curve shown by the heavy lines of Fig. 6(a). The stress distribution across any section of the wire while wound on the winding arbor will be as shown by the heavy lines of Fig. 6(b) where S_{YP} is the yield-point stress, the maximum stress that the material will sustain. The moment, across the section, required to produce this bending is

$$M = \int_{-h/2}^{h/2} Sbydy \qquad [21]$$

where b is the width of the wire at any point of y distance from the neutral axis and S is the stress at the same point. If the spring is released, it expands to a radius R_1 in which condition the external and the internal moments are both zero. It is now possible by applying the same moment as was given by Equation [21] to reduce the radius of curvature again to R_0 but without causing additional plastic flow. The added stress distribution produced by this second bending must therefore follow a straight line as shown by S_2-S_2, which together with the residual stresses in the relaxed condition (radius R_1) must equal the distribution S_{YP}-S_{YP} resulting from the original forming operation. Therefore the stress distribution in the relaxed condition (radius R_1) must be the difference between S_{YP}-S_{YP} and S_2-S_2 or as indicated in Fig. 6(c). The value of S_2 is of course so determined that the moment as specified by Equation [21] is the same for the dotted-line as for the solid-line stress distribution.

The value of $S_R = S_2$-S_{YP} is relatively easy to determine for rectangular and round wire, on the basis of the straight-line stress-strain characteristic if the bending has been sufficiently severe to have caused plastic flow almost to the neutral axis. The moment given by the actual stress distribution will then differ but little from that obtained by Equation [21] with S replaced by S_{YP}, a constant. The values of S corresponding to the S_2-S_2 distribution are given by

$$S = 2S_2y/h \qquad [22]$$

For a rectangular wire b is a constant and equating the moments corresponding to the two stress distributions gives

$$\int_{-h/2}^{h/2} S_{YP}bydy = \int_{-h/2}^{h/2} 2\,\frac{S_2}{h}\,by^2dy$$

from which $S_2 = (3/2)S_{YP}$ or

$$S_R = S_2 - S_{YP} = (1/2)S_{YP} \text{ (rectangular wire)} \qquad [23]$$

Similar integrations in the case of a round wire of radius $h/2$ for which $b = 2\sqrt{[(h/2)^2 - y^2]}$ gives

$$S_R = 0.7\ S_{YP} \text{ (round wire)} \quad [24]$$

These equations give the residual fiber stresses in the extreme inner and outer fibers under the assumed conditions. In any case where the stress-strain characteristic is known a correct value for the residual stress can be obtained by graphical integration. The values given by Equations [23] and [24] will however be fair approximations even in cases where the stress-strain characteristic is curved provided it does not exhibit strain hardening to a decided extent. Since a limited amount of plastic flow takes place for any stress above the proportional limit, which is generally far below the yield point, the residual stress may be sufficient to cause a small amount of creep. Any additional stresses will then cause permanent deformation of the spring.

The analysis will be continued on the basis of the idealized straight-line characteristic. Fig. 6(*d*) shows the result of placing the spring on the clutch arbor. The line S_0-S_0 shows the stresses added by this expansion where S_0 is given by Equation [20]. The sum of these stresses and those shown in Fig. 6(*c*) gives the total stresses as shown by the solid line of Fig. 6(*d*). If now a load be put on the clutch a uniform stress S_L will be added but this stress for even relatively light loads may be sufficient to cause the total stress on the inner fibers to exceed the yield point as is indicated in Fig. 6(*e*). The inner fibers are consequently stretched and when the load is released and the spring taken from the arbor it will be found that the center turns of the spring have expanded. Even with the spring on the arbor if the clutch is turned in the free direction it will be noticed that these center turns raise off the arbor. It was shown in the paragraphs on the clutch torque in the free direction that the torque did not increase appreciably after the first few turns. This can be explained by the fact that as soon as the outward radial force due to the compression along the wire is equal to the initial inward radial force of the spring on the arbor the friction on these turns vanishes. The value of the compression will be fixed by a relatively few end turns. Hence if the inward force of some of the center turns decreases due to their stretching this compression will be sufficient to expand the turns to clear the arbor. If S_L is still further increased the stretch will be sufficient to cause the diameter of the center turns to exceed the arbor diameter even when no torque is applied in the free direction.

Since the yield point of metals decreases at higher temperature it is possible to produce a spring having lower residual stresses by the proper heat-treatment. If the wire is wound on an arbor and then heated, additional plastic flow takes place since the maximum stress that can be sustained at the high temperature is that shown in Fig. 6(*a*) as the high-temperature yield point. If the spring is then cooled and released the expansion will not be as great as for the untreated spring. The residual stresses will again be given by Equation [23] or [24] where S_{YP} is taken as the lowest yield point reached in the temperature cycle. Fig. 7(*a*), (*b*), and (*c*) show the stresses in the heat-treated specimen corresponding to those shown in Fig. 6(*c*), (*d*), and (*e*) for the untreated spring. Fig. 7(*c*) shows that for the same load stress as for Fig. 6(*e*) no permanent deformation has taken place.

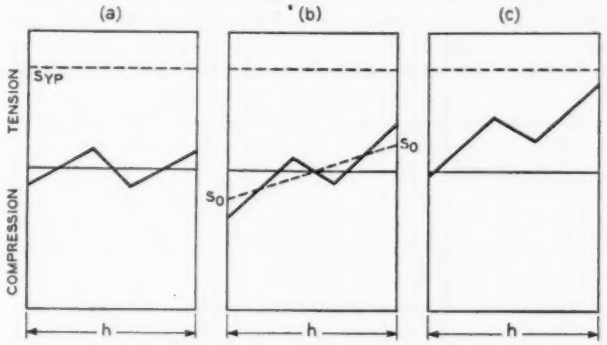

FIG. 7 STRESS CONDITIONS IN A STRAIN-ANNEALED CLUTCH SPRING

It is of course important that the strain-relieving temperature should not go high enough to lower permanently the strength of the material. This limit[2] for phosphor bronze is about 320 C.

TABLE 1 EFFECT OF HEAT-TREATMENT ON SPRINGS

Ribbons of 18-8 stainless steel, 0.0068 × 0.021 in., heat-treated on 0.1486-in. winding mandrels

400	4	0.175	47000

To determine the stress-temperature characteristics of 18-8 stainless steel[3] a number of springs of 0.0068 × 0.021-in. ribbon were wound on 0.1486-in. arbors and given various heat-treat-

[2] "Better Instrument Springs," by Robert W. Carson, Trans. A.I.E.E., vol. 52, September, 1933, p. 869.

[3] 8 per cent nickel, 18 per cent chromium.

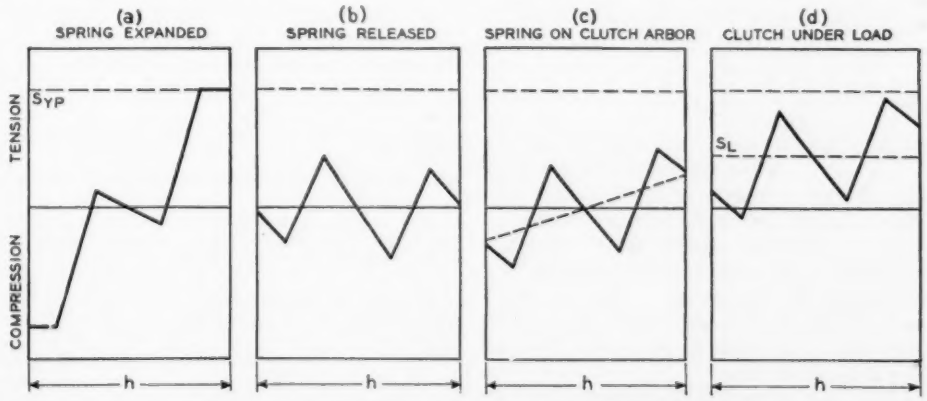

FIG. 8 STRESS CONDITIONS IN AN EXPANDED CLUTCH SPRING

ments. They were then cooled, released from the arbors, and measured for inside diameter. Table 1 gives the results of these measurements.

The residual stresses were calculated by noting from Equation [23] that $S_R = S_2/3$ and then obtaining S_2 from Equation [20] rewritten as

$$S_2 = \frac{h}{2R_1} \frac{R_1 - R_0}{R_0} E \quad \ldots\ldots\ldots\ldots [25]$$

Straight pieces of the stainless-steel ribbon were given the same series of heat-treatments as the springs. Young's modulus was determined for each of these samples and a bending test was also applied to determine whether the wire had been permanently annealed. No appreciable effect was noted. The proportional limit and the ultimate tensile strength of this ribbon at room temperature as measured on a tensile-testing machine were 41,600 and 252,000 psi, respectively. It is thus seen that except with the high-temperature anneals the residual stress alone exceeds the proportional limit and any additional stress will cause a permanent deformation.

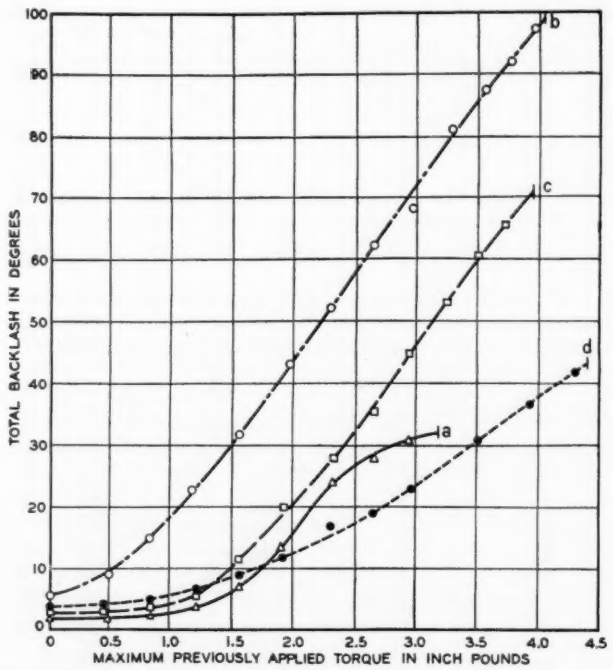

FIG. 9 EFFECT OF OVERLOAD ON CLUTCH BACKLASH. ARBOR DIAMETER, 0.190 IN.

(*a*) Phosphor-bronze-ribbon spring, 0.0085 × 0.022 in., heat-treated hr at 230 C, 0.1835 in. ID.
(*b*) 18-8 stainless-steel ribbon, 0.0068 × 0.021 in., wound on 0.127 in. mandrel and released, 0.183 in. ID.
(*c*) 18-8 stainless-steel ribbon, 0.0068 × 0.021 in., wound on 0.120-in. mandrel and released, 0.170 in. ID, mechanically expanded to 0.183 in. ID.
(*d*) 18-8 stainless-steel ribbon, 0.0068 × 0.021 in., wound on 0.157-in. mandrel, heated 4 hr at 470 C, cooled, and released, 0.182 in. ID.

To verify the validity of these arguments three springs of stainless-steel ribbon with different preliminary treatments and one of heat-treated phosphor bronze were tested for backlash as a function of previous loading. The backlash angle was measured from a point of slipping in the free direction to the point in the holding direction at which it would sustain a load of 0.05 in-lb. An initial load of 0.5 in-lb was then applied and removed and the backlash measured as before. This was repeated for various loads up to the breaking point of the spring. The results are shown in Fig. 9. In the case of the untreated stainless steel the backlash began to increase immediately. Its higher initial value was probably due to the unavoidable stressing occasioned by assembling the spring on the clutch arbor and to the 0.05-in-lb testing torque. The backlash of the other three samples remained constant to slightly above 0.5 in-lb and then began to rise. At low loads the phosphor bronze was better while at higher loads the heat-treated stainless steel had the advantage; the breaking load for the latter was also about 30 per cent higher.

CONCLUSION

The relations developed in the preceding sections are sufficient to determine uniquely the correct spring dimensions for a spring clutch of specified free and gripping torque provided the material constants and the cross-sectional shape (round or rectangular) of the wire as well as the length and diameter of the clutch arbor, are specified. Choice of values for the last two factors is based largely on permissible heating resulting from the slipping in the free direction. Furthermore, as would generally be the case, if only maximum values of the free torque and minimum values of the gripping torque are given a number of solutions can be obtained from which to choose the most convenient. By combining the relations derived, in a manner to permit step-by-step calculation, the design of spring clutches is reduced to a simple routine.

Boundary Friction in Bearings at Low Loads

By L. M. TICHVINSKY[1] and E. G. FISCHER,[2] EAST PITTSBURGH, PA.

The paper describes bearing tests performed in the region of semifluid or boundary lubrication. Bearings 2½ in. in diameter mounted in a rigid housing were loaded lightly and their performance studied in an attempt to correlate it with various physical properties of the bearing and journal materials. In this connection special consideration was given to journal surface finish and its measurement.

A CAREFULLY designed bearing performs well in the region of fluid lubrication. Such performance is characterized by a continuous viscous film possessing high load-carrying capacity. Due to accurate machining of the rigid journal and bearing also to correct selection of materials and lubricants the journal runs smoothly in the shell. It is separated from the latter by an oil film, the minimum thickness of which must be larger than the sum of the journal- and shell-surface irregularities (1).[3]

Such smooth bearing performance can be attained in bearings after they have gone through the short period of boundary or semifluid friction at the beginning of rotation before the continuous film is established. The same type of boundary friction must occur just before the full stop. These regions are indicated in Fig. 1 where the coefficient of friction f is plotted against the bearing characteristic number ZN/P. Z is the viscosity of the lubricant in centipoises, N = revolutions per minute, and P = bearing pressure on the projected area, pounds per square inch. The minimum oil-film thickness h_0 is also indicated, and is fully developed only in the region of fluid friction.

It is realized that a bearing performs under boundary conditions for only a very short interval. However, it can well be realized how detrimental such action might be due to wear of the sliding surfaces in the absence of a continuous oil film. Interesting experiments made in the National Physical Laboratory in England (2, 3) revealed that with sliding contact, high localized temperatures occur not only during dry-friction performance but also in the region of boundary lubrication. This high temperature undoubtedly accelerates local wiping and scoring of the bearing metal. In the boundary region the thin film separating the sliding surfaces has a thickness which is measured in terms of molecules. The unknown reactions between molecules of the fluid and surfaces determine the nature of the frictional resistance. Unfortunately little is known of the complex mechanism of boundary friction. Most experiments reveal that semifluid friction depends on a number of factors, such as adsorption, adhesion, and molecular orientation. Apparently in this type of friction adsorption plays a predominant role. The mechanism for lubrication becomes possible as a result of this physical property of the lubricating substance which causes it to adhere to the sliding surfaces. On two such surfaces the molecules of lubricant form continuous adsorption layers. A schematic representation of the adsorption layer made by Woog (4) often appears in the literature due to its simplicity and clearness. The boundary layers consist of molecules of lubricant that cling by their more active ends to the sliding surfaces, as shown in Fig. 2. The relative motion takes place on the sliding plane E, where the less active parts of the molecules meet and cause frictional resistance to decrease considerably. The magnitude of the forces which attract the active parts of molecules to the metal surfaces depends on the chemical properties of the lubricant and the type and finish of both the journal and the shell. For most of the organic compounds, to which all lubricants belong, the adhesion to such metals as steel, bronze, and babbitt is extremely high.

C and C', active parts of molecules
D and D', less active parts of molecules.

Because of this some physicists consider the adsorption layers to be firmly attached to the metal.

The bearing-testing apparatus used in this investigation incorporates many features common to actual bearing operation. For example, the sliding surfaces are curved, actual bearing and journal materials are used, and the grinding scratches of the journal are parallel to the direction of sliding motion. The authors endeavor to answer the questions: Does every kind of journal material and grade of finish give equal performance with the same babbitt shell? Does the boundary oil film formed on various combinations of bearing and journal materials have the same strength and frictional resistance?

Presented at the National Meeting of the Applied Mechanics Division of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1939, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

Test Setup

The tests were made on the bearing-testing machine shown in Fig. 3. The loading and torque-recording apparatus of the machine are shown schematically in Fig. 4. The bearings, as seen in Fig. 3, were mounted by means of steel bushings in a rigid housing made in two halves and bolted together. Interchangeable $2^1/_2$-in-diam journal sleeves, Fig. 5, were mounted on the shaft of the testing machine, Fig. 6. The shaft was mounted on two roller bearings and connected through a flexible coupling to a variable-speed motor, which provided a wide range of speed by means of armature and field voltage control.

Light bearing pressures up to 28 psi were applied by tightening the turnbuckle and the load was registered on the two spring scales P_L and P_R mounted parallel. An auxiliary weighing device was used to measure directly the friction torque in the

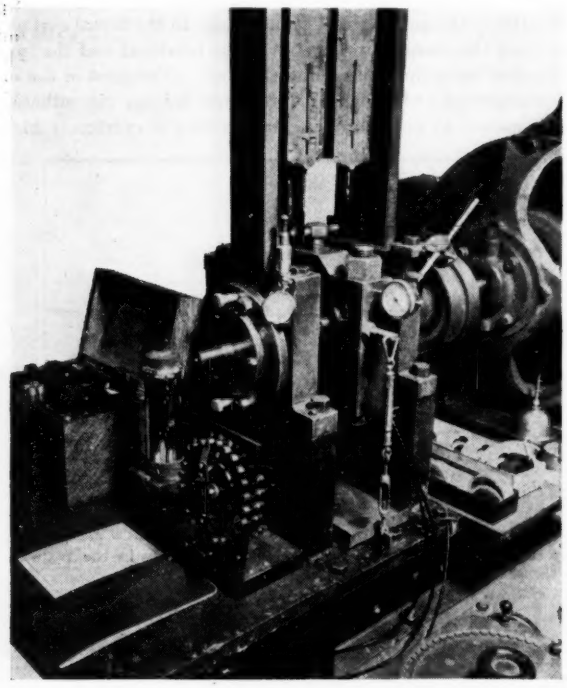

FIG. 3 MACHINE FOR TESTING BEARINGS

bearing. The zero position was previously set by the bubble level with the apparatus suspended free of the journal. When balanced, there was a negligible component of load opposing the bearing friction forces, and the weight of bearing housing and the friction pull were subtracted from the reading of the total suspended load.

Test Specimens

Journal sleeves were prepared from various shaft materials to the dimensions shown in Fig. 5. Measurements by micrometer caliper showed that all the 2.5-in-diam sleeves were ground within ±0.0005 in. A description of the journal materials used in the tests follows:

1 Nickel steel. Machined from a $2^3/_4$-in. round bar.

2 Free machining 18-8 steel. Machined from a 3-in. round bar.

3 Chromium steel, 12 per cent chromium, chromium-plated. Machined from a $2^3/_4$-in. round bar, ground to 2.495 in. OD, chromium-plated, above size, and reground to 2.500 in. OD.

4 Carbon steel sprayed with high-carbon steel. Machined

from a $2^3/_4$-in. round bar to 2.480 in. OD, sprayed oversize with 1.2 per cent carbon steel, and ground to size.

5 Carbon steel sprayed with 18-8 stainless steel. Machined from a $2^3/_4$-in. round bar to 2.480 in. OD, sprayed oversize with low-carbon 18-8 stainless steel, and ground to size.

6 Monel metal. Machined from $2^5/_8$-in. round bar.

The physical properties and chemical compositions of these materials are given in Tables 1 and 2.

Photographs of the surface finish of these journal sleeves were made by the optical method[4] before and after tests so that changes in the profiles could be measured. In Figs. 7 and 8 the upper photographs show the surface profiles of the six new journals, the lower, the same surface profiles after tests. All photographs were made with a magnification of about 280×. Each division of the scale shown on the profile photographs corresponds to 0.0002 in. The roughness of the journals, measured as the maximum depth of grinding scratches, is given in Table 3.

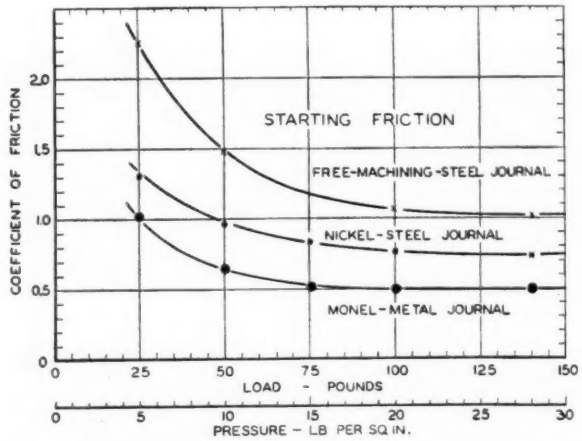

FIG. 11 PERFORMANCE OF THREE DIFFERENT JOURNALS IN A BEARING OF TIN-BASE BABBITT, STARTING FRICTION

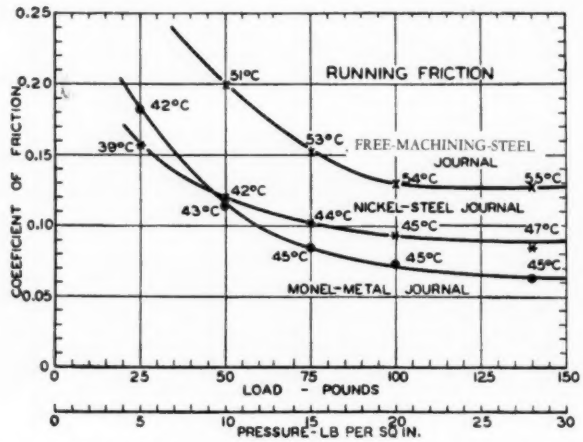

FIG. 12 PERFORMANCE OF THREE DIFFERENT JOURNALS IN A BEARING OF TIN-BASE BABBITT
(Running friction with boundary-layer lubrication.)

Properties of oils which were used during tests are shown in Fig. 10.

Method of Testing

The bearing machine was designed for investigating the condition of partial or boundary lubrication.

Before actual tests all bearings were satisfactorily run-in with oil (from 4 to 6 drops per minute of machine oil) inside of eight hours, during which time the load was increased to 28 psi at 600 rpm.

During the tests, torque measurements were made under starting and running conditions for various loads ranging from 25 to 140 lb (5 to 28 psi of projected area). Running-friction tests were made at 600 rpm (400 fpm) which allowed the maximum range of loading without excessive heating. The drop feed was

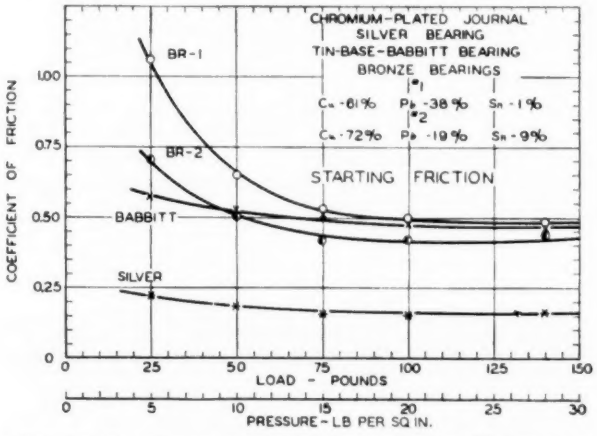

FIG. 13 PERFORMANCE OF DIFFERENT BEARING MATERIALS

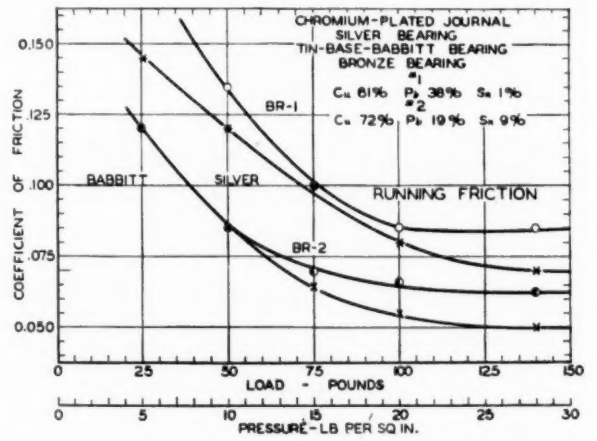

FIG. 14 PERFORMANCE OF DIFFERENT BEARING MATERIALS
(Running friction with boundary-layer lubrication.)

adjusted to provide enough oil for boundary lubrication but not enough to form a fluid film or to provide cooling.

Test Results

Figs. 11 and 12 show the values of the coefficient of friction, starting and running, respectively, for the three journal materials Nos. 1, 2, and 6. The temperatures shown next to each point on the curves for running friction indicate the final bearing-surface temperature for steady-state performance in still air. These journals were run in a tin-base-babbitt bearing. In both cases, starting and running, the free-machining steel showed the most friction, monel metal showed the least, and nickel steel was intermediate. These three materials have been arranged accord-

TABLE 5 COMPARISON OF JOURNAL MATERIALS

Sleeve no.	Material	Friction	Hardness, Brinell	Surface finish, microinches Before tests	After tests
6	Monel metal	Low	330	36	36
1	Nickel steel	Medium	217	89	80
2	Free-machining steel	High	180	133	89

ing to the values of friction, hardness, and roughness in Table 5.

It is of interest to note that the journal roughness, even at the low pressures used, decreased slightly during the running-in and actual test. The hardest material did not show any change in its surface qualities. The wear of the tin-base babbitt was not measured because of the light loads used. The visual examination did not show any wiping or scoring.

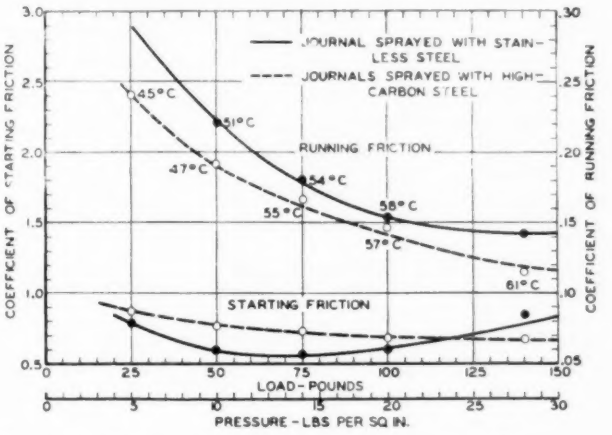

FIG. 15 PERFORMANCE OF SPRAYED JOURNALS IN A BEARING OF TIN-BASE BABBITT

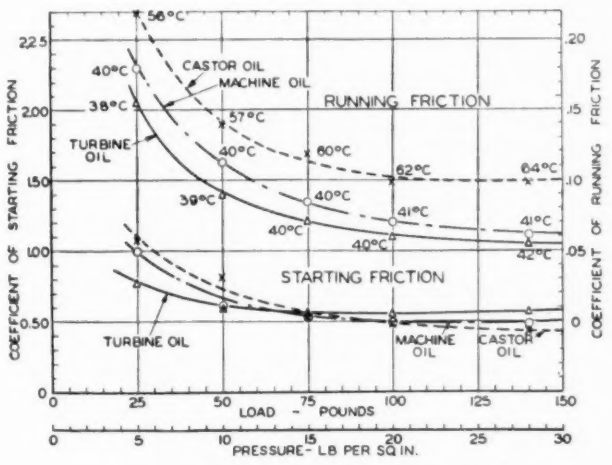

FIG. 16 EFFECT OF DIFFERENT LUBRICANTS
(Journal, monel metal; bearing, tin-base babbitt.)

Next, four different bearings were tested with one grade of journal material—No. 3, 12 per cent chromium steel, chromium-plated. As may be seen from Fig. 13 the silver bearing showed minimum value of starting friction while the three other materials performed at higher values. During running tests, Fig. 14, the babbitt and the high-tin high-copper bronze performed better than the silver or the high-lead bronze.

The performance of the two sprayed journals, Nos. 4 and 5, running in a tin-base-babbitt bearing is shown in Fig. 15. The starting and running friction are higher than for the low-friction materials shown in Figs. 11 and 12. As can be seen from Table 3, the originally high roughness of these two journals increased after tests.

The influence of lubricant is shown in Fig. 16. Under starting conditions the effect of the three oils is almost alike. It is of interest to point out the performance of the castor oil which shows a higher friction value at low pressure and a lower friction at higher pressures. During running conditions the friction values of the three oils are proportional to their respective viscosities.

Conclusion

Within the inherent limits of the experiment it was shown that various journal materials, similarly machined and ground, perform differently in a babbitt shell. A higher value of the coefficient of friction was associated with a relatively rougher journal finish having grinding scratches of the order of 100 microinches. Such finish in turn was associated with soft journal materials (180 Brinell).

The boundary oil film, formed between several grades of bearing materials and a chromium-plated journal, offered different frictional resistance to motion. In the combinations of different bearing materials and the same chromium-plated journal, babbitt proved to be superior to bronze or silver.

ACKNOWLEDGMENT

The authors are indebted to R. E. Peterson, manager, mechanics division, research laboratories and N. L. Mochel, metallurgical engineer, both of Westinghouse Electric & Manufacturing Co., who made these investigations possible. Dr. S. Way, of the research laboratories, helped in applying his method for the measurement of surface profiles.

Clamped Rectangular Plates With a Central Concentrated Load

By DANA YOUNG,[1] STORRS, CONN.

A GENERAL method of solution for rectangular plates with clamped edges and any kind of loading has been developed by Professor S. P. Timoshenko (1).[2] The present paper gives the results of calculations using this method for the maximum deflection, moment, and edge shears for rectangular plates of various proportions with all four edges clamped and loaded by a single concentrated load at the center. Similar data for a clamped rectangular plate with a uniformly distributed load have been given by I. A. Wojtaszak and also T. H. Evans (2). A report of an experimental investigation of this problem with some analytical results has been given by R. G. Sturm and R. L. Moore (3).

The notations used are as follows:

- a = length of plate in the x-direction
- b = length of plate in the y-direction
- h = thickness of plate
- E = modulus of elasticity of the plate material
- μ = Poisson's ratio. In the numerical calculations this is assumed equal to 0.3
- $D = \dfrac{Eh^3}{12(1-\mu^2)}$ is the flexural rigidity of the plate
- P = central concentrated load
- M = bending moment per unit length of plate
- Q = shearing force per unit length of plate
- R = total vertical reaction along one edge of plate
- w = deflection of plate at any point
- $\alpha_m = \dfrac{m\pi b}{2a}$
- $\beta_m = \dfrac{m\pi a}{2b}$

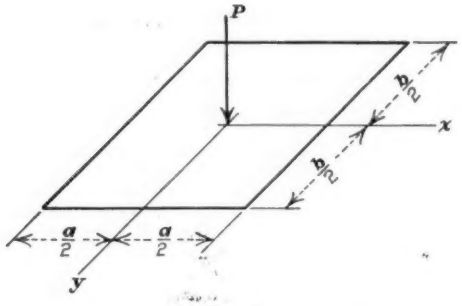

FIG. 1

The origin of coordinates is taken at the center of the plate as shown in Fig. 1. The general procedure as applied to this particular problem is as follows:

For a plate with no distributed lateral load, the deflection surface is governed by the differential equation

$$\frac{\partial^4 w}{\partial x^4} + 2\frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = 0 \quad \ldots\ldots [1]$$

To solve this equation for the given problem, the known solution for a simply supported plate with a central concentrated load is combined with that for a simply supported plate with distributed bending moments applied along the edges. The applied edge moments are then so determined that the slope at the boundaries is zero; that is, take

$$w = w_1 + w_2 + w_3 \quad \ldots\ldots [2]$$

where

$$w_1 = \frac{Pa^2}{2\pi^3 D}\sum_{m=1,3,5\ldots}\frac{1}{m^3}\cos\frac{m\pi x}{a}\left[\left(\tanh\alpha_m - \frac{\alpha_m}{\cosh^2\alpha_m}\right)\cosh\frac{m\pi y}{a} - \sinh\frac{m\pi y}{a} - \tanh\alpha_m\frac{m\pi y}{a}\sinh\frac{m\pi y}{a} + \frac{m\pi y}{a}\cosh\frac{m\pi y}{a}\right] \quad \ldots\ldots [3]$$

is the solution for a simply supported rectangular plate with a central concentrated load (4). Also where

$$w_2 = -\frac{a^2}{2\pi^2 D}\sum_{m=1,3,5\ldots}A_m\frac{(-1)^{\frac{m-1}{2}}}{m^2\cosh\alpha_m}\cos\frac{m\pi x}{a}\left[\frac{m\pi y}{a}\sinh\frac{m\pi y}{a} - \alpha_m\tanh\alpha_m\cosh\frac{m\pi y}{a}\right] \quad \ldots\ldots [4]$$

and

$$w_3 = -\frac{b^2}{2\pi^2 D}\sum_{m=1,3,5\ldots}B_m\frac{(-1)^{\frac{m-1}{2}}}{m^2\cosh\beta_m}\cos\frac{m\pi y}{b}\left[\frac{m\pi x}{b}\sinh\frac{m\pi x}{b} - \beta_m\tanh\beta_m\cosh\frac{m\pi x}{b}\right] \quad \ldots\ldots [5]$$

are the deflections for a simply supported plate with moments applied along the pairs of edges $y = \pm\dfrac{b}{2}$ and $x = \pm\dfrac{a}{2}$, respectively (5). These applied edge moments are given by

$$(M_y)_{y=\pm b/2} = \sum_{m=1,3,5\ldots}(-1)^{\frac{m-1}{2}}A_m\cos\frac{m\pi x}{a} \quad \ldots [6]$$

$$(M_x)_{x=\pm a/2} = \sum_{m=1,3,5\ldots}(-1)^{\frac{m-1}{2}}B_m\cos\frac{m\pi y}{b} \quad \ldots [7]$$

in which the Fourier-series coefficients A_m and B_m are to be determined from the condition that the slope at the boundaries

B_5	$0.0042\,P$	$0.0035\,P$	$0.0014\,P$	$-0.0015\,P$	$-0.0049\,P$	$-0.0083\,P$
B_7	$0.0015\,P$	$0.0018\,P$	$0.0018\,P$	$0.0019\,P$	$0.0021\,P$	$0.0027\,P$
B_9	$0.00055\,P$	$0.00066\,P$	$0.00061\,P$	$0.00045\,P$	$0.00019\,P$	$-0.00014\,P$
B_{11}	$0.00021\,P$					$0.00023\,P$
B_{13}	$0.00006\,P$					$0.00004\,P$

is zero. Thus taking $\left(\frac{\partial w}{\partial y}\right)_{y=b/2} = 0$ and expressing the terms containing $\frac{m\pi x}{b}$ $\sinh\frac{m\pi x}{b}$ and $\cosh\frac{m\pi x}{b}$ by a cosine series, we obtain

$$
\frac{Pa}{2\pi^2 D}\sum_{m=1,3,5\ldots}\frac{1}{m^2}\cos\frac{m\pi x}{a}\,\frac{\alpha_m\tanh\alpha_m}{\cosh\alpha_m} + \frac{a}{2\pi D}\sum_{m=1,3,5\ldots} A_m\,\frac{(-1)^{\frac{m-1}{2}}}{m}\cos\frac{m\pi x}{a}\left(\tanh\alpha_m + \frac{\alpha_m}{\cosh^2\alpha_m}\right) + \frac{4a^2}{\pi^2 bD}\sum_{m=1,3,5\ldots}\frac{B_m}{m^3}\sum_{i=1,3,5\ldots}\frac{i(-1)^{\frac{i-1}{2}}}{\left(\frac{a^2}{b^2}+\frac{i^2}{m^2}\right)^2}\cos\frac{i\pi x}{a} = 0 \ldots [8]
$$

This relation holds for any particular value of the cosine term, say $\cos\frac{k\pi x}{a}$. Therefore, the summation signs may be dropped and this cosine term canceled, thus obtaining

$$
A_k\frac{1}{k}\left[\tanh\alpha_k + \frac{\alpha_k}{\cosh^2\alpha_k}\right] + \frac{8ak}{\pi b}\sum_{m=1,3,5\ldots}\frac{B_m}{m^3}\frac{1}{\left(\frac{a^2}{b^2}+\frac{k^2}{m^2}\right)^2} = -P\,\frac{(-1)^{\frac{k-1}{2}}}{\pi k^2}\,\frac{\alpha_k\tanh\alpha_k}{\cosh\alpha_k} \ldots\ldots [9]
$$

Similarly, for zero slope at $x = \frac{a}{2}$ is obtained

$$
B_k\frac{1}{k}\left[\tanh\beta_k + \frac{\beta_k}{\cosh^2\beta_k}\right] + \frac{8bk}{\pi a}\sum_{m=1,3,5\ldots}\frac{A_m}{m^3}\frac{1}{\left(\frac{b^2}{a^2}+\frac{k^2}{m^2}\right)^2} = -P\,\frac{(-1)^{\frac{k-1}{2}}}{\pi k^2}\,\frac{\beta_k\tanh\beta_k}{\cosh\beta_k} \ldots\ldots [10]
$$

Equations [9] and [10] are used to determine the coefficients A_k and B_k. They form a double-infinite system of simultaneous equations which may be solved approximately by neglecting the higher terms. Thus for a plate with the proportions $b/a = 1.2$, from Equation [9] the system of Equations [11], given in Table 1, is obtained by assigning to k the values 1, 3, 5, ..., in turn. Similarly, from Equation [10] the system of Equations [12], given in Table 2, is derived.

Neglecting terms higher than those given, Equations [11] and [12] (Tables 1 and 2) may be solved by successive approximations. For the first approximation the terms to the right of the stepped line are neglected. For the second approximation, the values of A_3 to A_9 and B_5 to B_9 found from the first approximation are substituted in the terms to the right of the stepped line and the system solved again. This process is repeated as many times as necessary. Three or four approximations have been found sufficient for these calculations. Using this procedure, the coefficients for rectangular plates of several proportions were calculated. The results are given in Table 3.

The deflection at the center is then found from Equations [2], [3], [4], and [5] and may be reduced to the form

$$
(w)_{\substack{x=0\\y=0}} = \alpha\frac{Pa^2}{Eh^3} \ldots\ldots [13]
$$

The maximum edge moment is found from Equation [7] to be

$$
(M_x)_{\substack{x=\frac{a}{2}\\y=0}} = \sum_{m=1,3,5\ldots}(-1)^{\frac{m-1}{2}}B_m = -\beta P \ldots [14]
$$

in which the negative sign is used for a moment which bends the plate concave downward.

The maximum edge shear occurs at the center of the long side and is given by

$$
(Q_x)_{\substack{x=a/2\\y=0}} = -D\frac{\partial}{\partial x}\left(\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}\right)\Bigg|_{\substack{x=a/2\\y=0}} = -\gamma\frac{P}{a} \ldots [15]
$$

in which the negative sign denotes an upward shear at this point.

The total vertical reactions along the edges are given by

$$R_x = \int_{-b/2}^{b/2} (Q_x)_{x=a/2}\, dy = -\delta_x P \ldots\ldots\ldots [16]$$

The Thick-Film Lubrication of Full Journal Bearings of Finite Width

By M. MUSKAT[1] and F. MORGAN,[2] PITTSBURGH, PA.

A discussion is given of the results of analytical and experimental studies of the thick-film lubrication of full journal bearings of finite width. The Reynolds differential equation has been solved by a successive approximation method for (*a*) flooded full journal bearings, (*b*) full journal bearings with central circumferential grooves, and (*c*) full journal bearings provided with point sources of lubricant. Calculations were made on the variation of the journal eccentricity, load-carrying capacity, and friction coefficients with the Sommerfeld dimensionless variable for the three cases and for different bearing widths. Direct experimental tests are described which confirmed the theoretical predictions for bearings fed with lubricant at point sources.

ALTHOUGH the basic physical principles underlying the problem of lubrication were clearly outlined by Osborne Reynolds some fifty-three years ago, there still remains much to be done in the development of a complete understanding of the actual operation of modern industrial equipment. From the empirical point of view there has been a remarkably close approach to what may be considered as ideal performance. However, there appears to be little question but that the improvements in the actual operation of machines subject to lubrication have far outdistanced the advances in the physical theory as to just why and how these improvements are achieved.

From the physical point of view as well as from the practical aspects of the problem, the subject of lubrication conveniently divides itself into that pertaining to the so-called "thick-film" conditions of lubrication and that usually described as "thin-film" lubrication. In the former, which refers to conditions where the film of lubricant is of a thickness great as compared to the heights of the surface irregularities of the sliding parts, the film may be assumed to be nothing else than a hydrodynamic viscous liquid of a special geometry. Under thin-film conditions of lubrication, where the term "thin" indicates that the film thickness becomes of the order of the height of the projections upon the metallic surfaces, the detailed characteristics of these surface irregularities and the nature of the metallic surfaces will play roles as important as, if not predominant over, those of the properties of the lubricant which normally characterize it as a viscous liquid. This latter part of the subject, though of greater importance from a practical point of view, is obviously more complex physically. Much excellent work on it has been described in the recent literature, but it has not yet been subjected to a comprehensive correlation and formulated into a unified physical and quantitative theory.

Thick-film lubrication, on the other hand, involves only the hydrodynamic behavior of the lubricant film, and is therefore much simpler from the physical point of view. Mathematically, however, it may still be considered as a formidable problem, and much work yet remains to be done in developing all the implications of what are otherwise rather simple physical postulates regarding this type of lubrication. As a preliminary approach to the more practical thin-film phases of the problem the authors have begun a study of the hydrodynamics of thick-film lubrication, which it was hoped might provide a desirable and helpful background in investigating later the more complex features of the thin-film region. Some of the preliminary developments in this study will be reported here.

In order to interpret correctly the implications of experimental data on thick-film lubrication with regard to the validity of the hydrodynamic theory, one must obviously have available the predictions of the latter under the experimental conditions being studied. In the case of journal bearings this means that solutions of the hydrodynamic equations must be derived for bearings of finite width, since all practical and experimental bearings will necessarily be of finite width. As the standard solutions previously available for journal-bearing lubrication referred to the infinitely wide bearing originally treated by Reynolds and Sommerfeld, it was necessary to develop first the corresponding analysis for the bearings of finite width.

This discussion will not enter into the mathematical details but will be confined essentially to the final results.[3] These results are the direct consequences of the solution of the Reynolds equation, which may be expressed in dimensionless form as

$$\frac{\partial}{\partial\theta}\left\{(1+\eta\cos\theta)^3\frac{\partial p}{\partial\theta}\right\}+(1+\eta\cos\theta)^3\frac{\partial^2 p}{\partial w^2}=-\beta\eta\sin\theta \quad [1]$$

where p is the pressure distribution in the film, θ the azimuthal angle in the direction of rotation, and η, w, and β are defined by

$$\eta=\frac{e}{c};\quad w=\frac{z}{r};\quad \beta=6\mu Ur/c^2 \quad [2]$$

Here e is the displacement between the axes of the journal and bearing, c is the radial clearance, z the axial coordinate, r the journal radius, μ the lubricant viscosity, and U the surface velocity of the journal, as indicated in Fig. 1. The film thickness is taken as

$$h=c+e\cos\theta \quad [3]$$

Equation [1] was solved by a successive approximation method in which all the physical quantities of interest were expanded in powers of the eccentricity η. That is, p was first expressed formally as

$$p(\theta, w)=\Sigma\eta^m p_m(\theta, w) \quad [4]$$

This was inserted in Equation [1] and after expanding the various

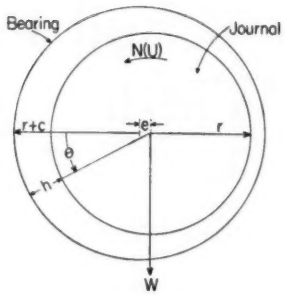

FIG. 1 CROSS SECTION OF A FULL JOURNAL BEARING

terms the coefficients of like powers of η were equated. The following series of Poisson equations for the $p_m(\theta, w)$ was thus obtained

$$\left.\begin{aligned}
\nabla^2 p_0 &= \frac{\partial^2 p_0}{\partial \theta^2} + \frac{\partial^2 p_0}{\partial w^2} = -\beta\eta \sin\theta \\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\
\nabla^2 p_m &= -3\left(\cos\theta \nabla^2 p_{m-1} - \sin\theta \frac{\partial p_{m-1}}{\partial \theta}\right) \\
&\quad -3\cos\theta\left(\cos\theta\nabla^2 p_{m-2} - 2\sin\theta\frac{\partial p_{m-2}}{\partial\theta}\right) \\
&\quad -\cos^2\theta\left(\cos\theta\nabla^2 p_{m-3} - 3\sin\theta\frac{\partial p_{m-3}}{\partial\theta}\right)
\end{aligned}\right\} \quad \ldots[5]$$

These equations were then solved successively in analytical form. For the solutions involving only β, corresponding to flooded bearings or bearings with circumferential grooves, the first five equations of the series were solved. For the solutions involving point sources of lubricant the solutions of only the first three equations were derived explicitly.

Once the pressure distribution was found, the load supported by the film was calculated by integrating the pressure components parallel and perpendicular to the polar axis, i.e., by the integrals

$$\begin{matrix} P_\parallel \\ P_\perp \end{matrix} \int_{-\bar{w}}^{\bar{w}} dw \int_0^{2\pi} p \begin{matrix} \cos\theta \\ \sin\theta \end{matrix} d\theta \quad \ldots\ldots\ldots\ldots[6]$$

where $\bar{w}$ represents the dimensionless half width of the bearing, i.e., the width divided by the diameter.

The frictional forces required to keep the journal in rotation or the bearing stationary were calculated by integrating the surface stresses in the film over the journal and bearing surfaces.

In the final application and interpretation of the analysis, particular attention has to be paid to the character of the source of lubricant with which the system is provided. Thus far the detailed calculations have been carried through for the three cases where: (1) The bearing is flooded and has no external lubricant source, (2) the bearing is provided with a central circumferential groove as a lubricant source, and (3) the lubricant is fed to the bearing through a small circular hole, which was represented mathematically as a point source, somewhere along the central circumference of the bearing. As the results differ markedly in these various cases they will be discussed separately.

FLOODED FULL JOURNAL BEARINGS

With regard to the pressure distribution itself it was found that in the case of flooded full journal bearings the pressure distribution over the semicylinder on one side of the line of centers was the exact negative reflection of that on the semicylinder on the other side of the line of centers. As an immediate consequence the resultant load which could be supported by the film is normal to the line of centers, so that when the external load is applied vertically the displacement of the journal in the bearing must lie along the horizontal. This situation is exactly the same as in the case of the infinitely wide bearing originally treated by Sommerfeld.

The variation in the position of the center of the journal may best be seen by plotting the value of the journal eccentricity η against the dimensionless Sommerfeld variable, $S = (r/c)^2\mu N/P$, where P is the load per unit projected bearing area and N is the speed in rps. The practical significance of this variable is that it may be used to specify roughly the thick- and thin-film

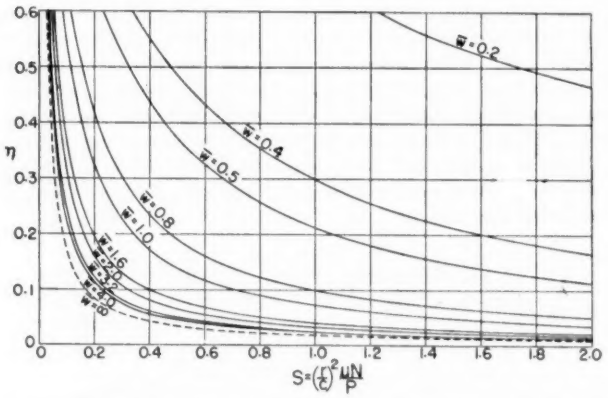

FIG. 2 THE VARIATION OF THE JOURNAL ECCENTRICITY η WITH THE SOMMERFELD VARIABLE S FOR FLOODED JOURNAL BEARINGS OF FINITE WIDTH

[$\bar{w}$ = (bearing width)/(bearing diameter); r = journal radius; c = radial clearance; μ = lubricant viscosity; N = journal speed, rps; P = load per unit projected bearing area.]

ranges of lubrication. Thus when $S > 0.05$, viscous or thick-film conditions will usually obtain, while values of $S < 0.05$ will as a rule correspond to partial or thin-film lubrication, although these limits are by no means rigidly applicable under all conditions. The numerical results for the flooded full journal bearing are shown in Fig. 2 for different bearing widths defined by the parameter $\bar{w}$ which, as already indicated, is equal to the actual bearing width divided by the bearing diameter. The dotted curve in Fig. 2 represents the values given by the Sommerfeld theory for the infinitely wide bearing.

It will be seen that the eccentricity assumed by a bearing of finite width for a given value of S is uniformly higher than that for the infinitely wide bearing. Moreover this eccentricity increases as the bearing width decreases. This is of course due to the fact that the dropping off of the pressure to atmospheric at the ends of the finite-width bearing leads to smaller average pressures in the bearings of short width, which in turn necessitate greater eccentricities and wedging effects to permit the support of loads of the same magnitude. This effect may be seen more clearly by computing the relative load-carrying capacities of the finite-width bearings and the infinitely wide bearing having the same journal eccentricity. Assuming equal values of r/c, μ, and N, the load-carrying capacity will clearly be proportional to the reciprocal of the Sommerfeld variable. The relative load-carrying capacities will therefore be given simply by S_0/S, where S_0 and S are given by the abscissas of the dotted and solid curves of Fig. 2. Such comparisons are shown graphically in Fig. 3 for different values of $\bar{w}$.

As Fig. 3 shows, the relative load-carrying capacities for fixed eccentricities of the finite-width flooded bearings are uniformly less than one. Moreover, the load-carrying capacity decreases

continuously with decreasing bearing width. Thus, for a bearing width equal to the bearing diameter ($\bar{w} = 1$), the load-carrying capacities for the same eccentricity will be of the order of from 25 to 30 per cent of those of the infinitely wide bearing, and for a bearing width equal to one half the diameter, the load-carrying capacities will fall to less than 10 per cent of the infinitely wide bearing values. These results may be contrasted with the values $2/3$ and $2/\pi$, for all values of η, obtained on the common assumptions that the axial pressure distributions fall in parabolic or trigonometric manner, respectively, from the Sommerfeld distribution along the central circumference.

While these results do show the importance of taking into account the "end effects" of the finite-width bearing and the associated dropping off of the pressure distribution to atmospheric at the ends, they do not necessarily imply corresponding differences in ultimate load-carrying capacities of the finite-width journal bearings. Rather they give only the relative values of the load-carrying capacity of the finite-width bearings as compared to those for the infinitely wide bearing for the same value of η, that is, *the same geometry*. All that would be necessary, to obtain in a finite-width bearing any predetermined load-carrying capacity corresponding to an infinitely wide bearing with fixed

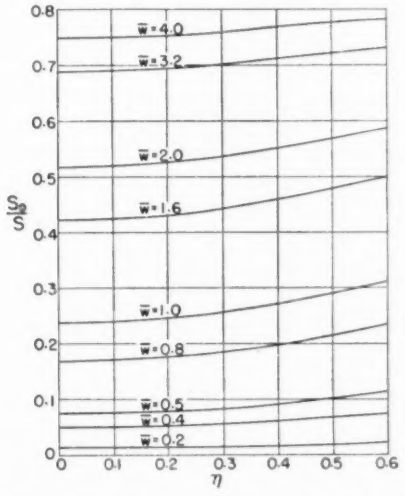

FIG. 3 RELATIVE LOAD-CARRYING CAPACITIES OF FLOODED JOURNAL BEARINGS OF FINITE WIDTH

[S_0/S = (load-carrying capacity of finite-width bearing)/(capacity of infinitely wide bearing of same eccentricity); $\bar{w}$ = (bearing width)/(bearing diameter).]

eccentricity, would be to increase the eccentricity of the former. In principle, it will be possible to obtain arbitrarily large load-carrying capacities with the finite-width bearing to the same extent that such would be possible with bearings of infinite width, although from a practical point of view, the higher eccentricities that would be required in the case of a finite-width bearing might lead to seizing or scoring of the bearing somewhat earlier than under the hypothetical case of the infinitely wide bearing.

The results of the calculation for the friction coefficient on the journal are shown in Fig. 4, in which the dotted curve again refers to the case of the infinitely wide bearing. It will be seen that in general the friction coefficients for the finite-width bearing are higher than those for the infinitely wide bearing, and that the difference increases as the bearing width decreases. Asymptotically, however, they all approach the Petroff line through the origin, of slope $2\pi^2$. The reason for the higher friction coefficients for the finite-width bearings obviously lies in the higher eccentricities previously noted for fixed values of S.

These results are valid for relatively large values of S, i.e., for those corresponding to values of the eccentricity not exceeding 0.6. To obtain the corresponding information in the thin-film

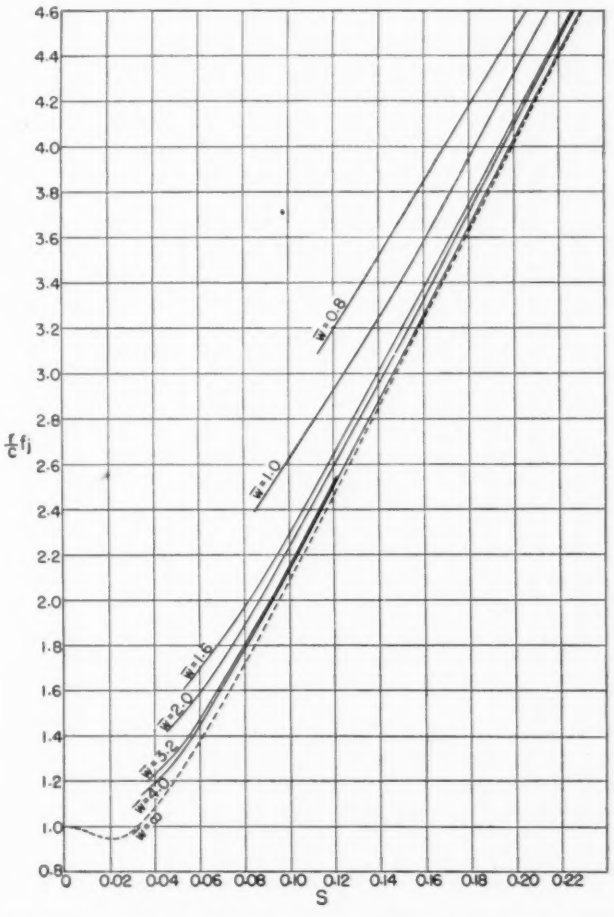

FIG. 4 FRICTION COEFFICIENTS ON THE JOURNAL fj VERSUS S FOR FLOODED BEARINGS OF FINITE WIDTH

[$\bar{w}$ = (bearing width)/(bearing diameter); c = radial clearance; r = journal radius. Dotted curve represents Sommerfeld curve for infinitely wide bearing.]

region or for values of the eccentricity approaching 1, different analytical procedures must be used.

FULL JOURNAL BEARINGS WITH CENTRAL CIRCUMFERENTIAL GROOVES

While at first thought the case of a full journal bearing with a central circumferential groove may appear to demand a considerably more complex analysis than that required for the flooded journal bearing, it turns out that the difference in the analytical solutions for the two cases consists merely in the almost trivial addition of a linear axially varying pressure term which takes into account the presence of the circumferential groove. For all that such a groove actually does is to split the original bearing into two end-fed bearings, with the fed ends adjacent to the groove. The pressure distributions in such end-fed bearings are identical with those in the flooded bearing with the same journal eccentricity, except for the variation in pressure parallel to the axis, which is induced by the end feed. However, this linear axial pressure term does not affect the load that can be supported by the film, nor does it affect the friction properties. The line of centers in the bearing with the circum-

ferential groove will therefore also remain horizontal if the load be vertical.

The only ultimate effect of the circumferential groove is to reduce the composite bearing with the groove to two flooded bearings of half the original bearing width. The detailed properties, such as the variation of the journal eccentricity with S or of the friction coefficient with S will be given by exactly the same numerical results already derived for the flooded bearings, provided only that the effective width of the flooded bearing be taken to be half of the true width of the composite bearing. In other words, for a bearing with a circumferential groove for which the over-all dimensionless width = 1, the curve of η versus S will be exactly the same as that shown in Fig. 2 for the case of a dimensionless width equal to $^1/_2$ or $\bar{w} = 0.25$. The same relationship will obtain with respect to the load-carrying capacities of the bearing as shown in Fig. 3, and the friction-coefficient curves as shown in Fig. 4. In short, a circumferential groove in a bearing cuts the effective bearing width in half—except for the actual width of the groove—with respect to its load-carrying power and friction properties. As will be seen from Figs. 2, 3, and 4, the magnitude of this effect is much larger than that which could be attributed to merely cutting the width of the composite bearing by the width of the groove, especially if the bearings are initially of relatively short width.

Because of the lower load-carrying capacities and higher friction coefficients of the flooded bearings of short width it follows that from a strictly hydrodynamic point of view a circumferential groove would impair the lubricating effectiveness of a journal bearing. However, there are two considerations pertinent to the practical use of journal bearings which may offset these hydrodynamic disadvantages of the circumferential groove.

The first is that the higher rate of lubricant flow through a bearing with such a groove will tend to cool the lubricant film and thus maintain a higher viscosity of the lubricant. This in turn will lead to higher load-supporting capacity of the film as compared to that in a flooded bearing where the film temperature may become high and the viscosity low. This effect may be especially important when the bearing is operated under thin-film conditions, when the fall in lubricant viscosity due to the temperature rise would tend to aggravate the tendency for metallic contact to develop and ultimately cause seizing or scoring of the bearing.

An even more valuable practical feature of the circumferential groove may result from the possibility of overcoming the negative pressures in the lubricant film by means of the added feed pressure applied at the groove. For in the theoretical hydrodynamic film the pressures over the bearing surface on one side of the line of centers of the journal and bearing are just as much below atmospheric as those on the other half are above atmospheric. If there is no external feed pressure applied to overcome these negative pressures the film may break and thus cut down the load-supporting power. As the feed pressures in the circumferential groove are uniformly distributed over the whole periphery of the bearing they will tend to overcome the negative pressures that would theoretically obtain in the flooded bearing, thus preventing the breaking of the film and permitting it to support the full value of the load as predicted by the hydrodynamic theory.

Full Journal Bearings Fed With Lubricant at Point Sources

In contrast to the case of the feed pressure as applied to a circumferential groove, a pressure applied at a point source dissipates itself rapidly in moving away from the location of the source to the distant parts of the film. Nevertheless such point sources of lubricant may exert significant reactions upon the behavior of the lubricated system. The exact effects depend upon the position of the lubricant source as well as upon its strength q_0, to which reference is made later. For the present purpose it will suffice to consider only the two cases where the source is set through the vertical line of application of the load, and either at the crown of the bearing or unloaded part of the film, or at the base of the bearing or the loaded part of the film. It is supposed that the actual load is applied to the journal.

When the source is at the crown of the bearing it is found that its general effect is to cause a displacement of the journal still greater than that merely corresponding to its rotational position. This in turn leads to higher journal eccentricities than for the case of the flooded bearing, correspondingly lower load-carrying capacities for fixed eccentricity, and higher values of the friction coefficient for fixed values of the Sommerfeld variable. As in the case of the flooded bearing the journal eccentricity, load-carrying capacity, and friction coefficient all depend upon the actual value of the bearing width, and moreover vary also with the strength of the lubricant source. Thus the relation between the friction coefficient and the Sommerfeld variable is not given by a universal curve applicable under all conditions with deviations implying the presence of oiliness effects, but rather the Sommerfeld variable appears to be but one parameter required for the complete specification of an actual bearing system of finite width.

When the lubricant source is set at the base or the loaded part of the bearing its effect is radically different. Here it tends to increase the load-carrying power of the film arising from the journal rotation and lessens the eccentricity required to support any given load. In fact if the source strength is made sufficiently high so as to attain a certain critical value the pressure distribution due to the lubricant source will suffice alone to carry the whole of the external load without any need for the supporting effect due to the journal rotation. Under such circumstances the journal becomes concentric with the bearing so that the load-supporting power of the film due to the rotation automatically vanishes. And when the source strength is increased still further the journal is raised beyond its central position, forcing the rotational effect to give a load-depressing component so as to counterbalance some of the load-supporting forces due to the lubricant source. The displacement of the journal center will no longer lie along the horizontal, but will move into any of the four quadrants, depending upon the actual strength of the lubricant source, its position, and the value of the Sommerfeld variable.

Perhaps the most striking effect of the lubricant source when placed at the base of the bearing is its ability to eliminate completely all thin-film effects normally encountered when the Sommerfeld variable becomes vanishingly small. For with the lubricant source set in the loaded part of the bearing the journal can be supported without coming into metallic contact with the bearing surface even though the rotation of the journal ceases. The resting position of the journal under such conditions will of course depend upon the strength of the source, and the ultimate separation between the journal and bearing surfaces will increase as the source strength increases. When the critical value previously mentioned is reached, the two will become concentric whether the journal is rotating or not.

With regard to the coefficient of friction, it will in general be decreased by a source set at the base of the bearing as long as the source strength is less than the critical value required to support the load completely. For higher values of source strength the friction coefficient begins to increase, and ultimately it may even exceed the values appropriate to flooded journal bearings.

Experimental Studies

The essential features of the theoretical predictions for journal-bearing systems fed with lubricant at point sources have been confirmed by direct experimental tests. These experiments were performed with a machine shown diagrammatically in Fig. 5. The Graham variable-speed transmission driving the journal provided a continuous variation of speeds from 0 to 680 rpm. The bearing was $9^3/_4$ in. wide and $3^1/_2$ in. in diameter. The ratio of the journal radius to the radial clearance was 1470. Two oils and diethylbutyl alcohol were used as the lubricants, the viscosities of which at 25 C varied from 51.1 to 3.2 centipoises. The load was varied from 61.7 to 215.4 lb. The film

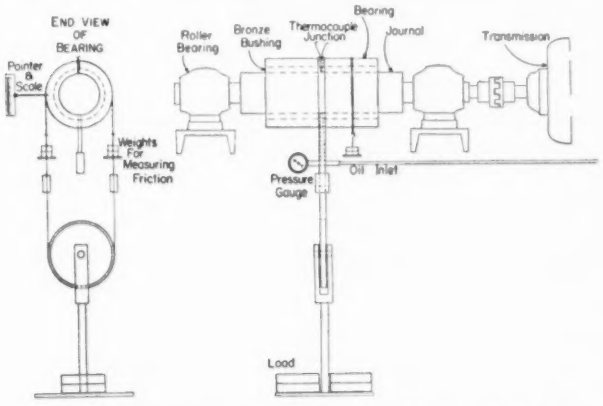

Fig. 5 Diagrammatic Representation of Machine for Measuring Journal-Bearing Friction

viscosity was determined by means of a thermocouple junction set flush with the bearing surface. The rate of flow of lubricant through the bearing was measured by collecting the leakage out of its ends in drains from which it flowed into a burette. Experiments were performed both with the source set at the crown of the bearing and at the base, and the torque was measured on the bearing.

A typical set of results is shown in Fig. 6, which was obtained with the source set in the loaded part of the bearing. The parameters q_0 indicate the values of the dimensionless flux strength appearing in the theoretical analysis as the quantity characterizing the strength of the lubricant source. It was calculated by means of the formula

$$q_0 = 3\mu Qr^2/\pi c^3 W \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots [7]$$

where Q was the actual rate of lubricant flow through the bearing and W the total load.

In contrast to friction-coefficient curves previously published in the literature, which, at high values of S, approach straight lines with positive intercepts on the friction axis, all the curves of Fig. 6 asymptotically approach the Petroff line of slope $2\pi^2$ passing through the origin, as theoretically predicted. Moreover, as the analysis requires, the curve for the critical source strength $q_0 = 0.091$ follows this Petroff line throughout its whole extent, since for this value of q_0 the source should alone be able to support the whole of the load and the journal should run concentrically in the bearing. The experimental data also verify the theoretical prediction that the friction coefficient on the bearing for a fixed value of the Sommerfeld variable uniformly increases as the source strength increases when the source is in the loaded

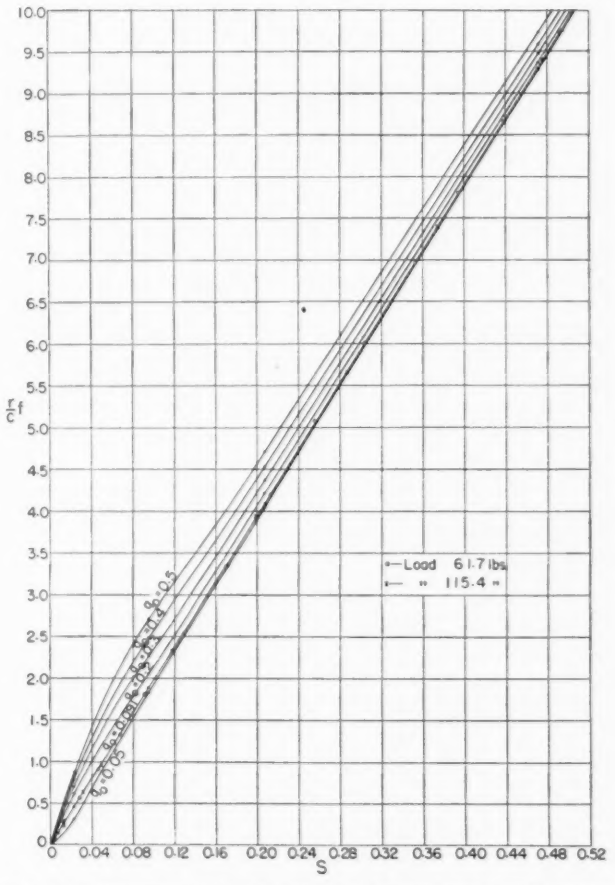

Fig. 6 Experimentally Determined Coefficients of Friction on the Bearing Versus S
(q_0 = dimensionless source strength.)

part of the bearing. Finally it will be seen that for this position of the lubricant source all the friction curves are directed so as to pass through the origin with vanishing value of the Sommerfeld variable, without encountering the slightest indication of the usual thin-film phenomena. And it may be added that, again in accordance with the theoretical prediction, the thin-film behavior does appear at low values of the Sommerfeld variable when the source is placed in the unloaded part of the bearing.

It would be misleading to claim that the theory as thus far developed agrees completely in quantitative detail with the experimental findings under all conditions. Deviations have been found at high values of the source strength and at very low values of the Sommerfeld variable. These discrepancies, however, do not at all necessarily imply a breakdown of the hydrodynamic picture, but rather may be reasonably correlated, both with the inherent approximations of the mathematical analysis and some of the unavoidable uncertainties and errors in the experimental determinations. But with respect to all the essential major features of the problem, the experiments do show that the Reynolds hydrodynamic equations provide a satisfactory physical explanation of journal-bearing lubrication obtaining under thick-film conditions.

A Theory of Flexure for Beams With Nonparallel Extreme Fibers

By WILLIAM R. OSGOOD,[1] WASHINGTON, D. C.

A theory of flexure for beams with nonparallel extreme fibers is presented. The theory is shown to reduce to the ordinary theory of flexure as the angle between the extreme fibers approaches zero. Maximum fiber stresses computed by the theory and by the ordinary theory for a plate girder with nonparallel flanges show that for angles between the flanges up to twenty degrees the ordinary theory can never be in error more than about five per cent, but for larger angles the error in general increases rapidly with the angle. Finally an example is given of the application of the theory as an approximation to a beam with curved extreme fibers. In this case the theory was confirmed by the results of tests.

Introduction

THE ANALYSIS of the stresses in a beam with nonparallel extreme (top and bottom) fibers arises occasionally as a problem in structural design. The ordinary beam theory is commonly used in such an analysis and, when the extreme fibers are nearly parallel, this theory is good enough for practical purposes. It cannot but be seriously in error when the extreme fibers are far from parallel. An accurate theory exists for a very narrow or a very wide wedge with plane parallel ends loaded at its edge. This theory can be extended to a wedge with nonparallel but symmetrical ends, with a degree of approximation which should be comparable to that of the ordinary beam theory applied to an ordinary beam with nonparallel sides (in the plane of bending). It is of interest to compare extreme-fiber stresses obtained by this extended theory with those obtained by the ordinary beam theory applied to the wedge. Furthermore, recent tests[2] indicate that the theory of the wedge may be exploited to yield satisfactory results in cases where the extreme fibers are not only not parallel but not straight.

Equations of Equilibrium and Compatibility

When it is justifiable to assume a condition of plane stress in a disk of nonuniform thickness, the equations of equilibrium in polar coordinates become in the absence of body forces[3]

$$\left.\begin{aligned} \frac{\partial(\sigma_r t)}{\partial r} + \frac{1}{r}\frac{\partial(\tau_{r\theta} t)}{\partial \theta} + \frac{\sigma_r t - \sigma_\theta t}{r} &= 0 \\ \frac{1}{r}\frac{\partial(\sigma_\theta t)}{\partial \theta} + \frac{\partial(\tau_{r\theta} t)}{\partial r} + \frac{2(\tau_{r\theta} t)}{r} &= 0 \end{aligned}\right\} \quad \ldots\ldots\ldots [1]$$

where t is the thickness of the disk at any point, and the other notation is well known. The equation of compatibility remains unchanged[3]

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2} + \frac{1}{r}\frac{\partial}{\partial r}\right)(\sigma_r + \sigma_\theta) = 0 \quad \ldots\ldots\ldots [2]$$

The Theory of the Wedge

Consider a wedge, Fig. 1, having an arbitrary symmetrical circular-cylindrical section, as shown by arc A-A. The thickness t is assumed not to vary radially. If it does, the following analysis may be expected to be in error by an amount comparable to the error in the ordinary beam theory when applied to a similar straight beam of which symmetrically situated elements (fibers) of the sides are not parallel. Introduce a system of polar coordinates r, θ with the pole at the edge of the wedge and the

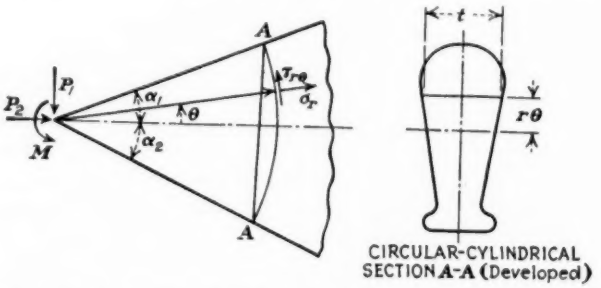

FIG. 1 SIDE ELEVATION AND SECTION OF WEDGE-SHAPED BEAM

polar axis in a temporarily arbitrary direction. Take the wedge to be loaded at the edge by a force P_1 perpendicular to the polar axis, a force P_2 along the polar axis, and a couple M, all positive as shown. The loads will be considered one at a time, and the stresses due to them may then be added by the principle of superposition. The equation of compatibility, Equation [2], is satisfied in each case.

The theory of the wedge with plane parallel ends[3] suggests that the radial stress σ_{r1} due to the force P_1 may be given by $\sigma_{r1} = (c_1/r)\sin\theta$, where c_1 is a constant, and that the tangential stress $\sigma_{\theta 1} = 0$ everywhere. The equations of equilibrium [1] together with the condition that the sides of the wedge are free from stress then require the shearing stress $\tau_{r\theta 1}$ to be everywhere zero. The solution for this case is therefore of the form

$$\sigma_{r1} = (c_1/r)\sin\theta, \quad \sigma_{\theta 1} = 0, \quad \text{and } \tau_{r\theta 1} = 0 \ldots [3]\,[4]\,[5]$$

and it only remains to locate the polar axis and to determine the constant c_1, which may be done with the aid of the conditions of equilibrium (forces parallel and perpendicular to the polar axis) of the portion of the wedge between the edge and the circular-cylindrical section A-A

$$\int_{-\alpha_2}^{\alpha_1} \sigma_{r1} t r \cos\theta \, d\theta = 0$$

Presented at the National Meeting of the Applied Mechanics Division of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until October 10, 1939, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[3] See for example "Theory of Elasticity," by S. Timoshenko, McGraw-Hill Book Company, New York and London, 1934, chap. 3.

and $$\int_{-\alpha_2}^{\alpha_1} \sigma_{r1} tr \sin\theta \, d\theta - P_1 = 0$$

that is, $$\int_{-\alpha_2}^{\alpha_1} t \sin 2\theta \, d\theta = 0 \quad \ldots\ldots [6]$$

and $$c_1 \int_{-\alpha_2}^{\alpha_1} t \sin^2\theta \, d\theta - P_1 = 0 \quad \ldots\ldots [7]$$

Since $\alpha_1 + \alpha_2$ together with t as a function of θ are supposed known, Equation [6] will give α_1 or α_2, thus locating the polar axis, and Equation [7] will then give c_1.

Just as in the case of the force P_1, the theory of the wedge with plane parallel ends[3] suggests that the radial stress σ_{r2} due to the force P_2 may be given by $\sigma_{r2} = (a_1/r)\cos\theta$, where a_1 is a constant, and that the tangential stress $\sigma_{\theta 2} = 0$ everywhere. Again as before, Equations [1] together with the condition that the sides of the wedge are free from stress require the shearing stress $\tau_{r\theta 2}$ to be everywhere zero. The solution for this case is therefore of the form

$$\sigma_{r2} = (a_1/r)\cos\theta, \quad \sigma_{\theta 2} = 0, \quad \tau_{r\theta 2} = 0 \ldots [8]\ [9]\ [10]$$

and it remains to locate the polar axis and to determine the constant a_1, which may be done in the same way as previously with the aid of the conditions of equilibrium (forces perpendicular and parallel to the polar axis) of the portion of the wedge between the edge and the circular-cylindrical section A-A.

$$\int_{-\alpha_2}^{\alpha_1} \sigma_{r2} tr \sin\theta \, d\theta = 0 \text{ and } \int_{-\alpha_2}^{\alpha_1} \sigma_{r2} tr \cos\theta \, d\theta + P_2 = 0$$

that is, $$\int_{-\alpha_2}^{\alpha_1} t \sin 2\theta \, d\theta = 0 \quad \ldots\ldots [11]$$

and $$a_1 \int_{-\alpha_2}^{\alpha_1} t \cos^2\theta \, d\theta + P_2 = 0 \quad \ldots\ldots [12]$$

Equation [11] is the same as Equation [6], and thus the direction of the polar axis is independent of the line of action of any force acting at the edge of the wedge. The constant a_1 can be obtained from Equation [12] as soon as the polar axis has been located from Equation [11].

The theory of the wedge with plane parallel ends[4] suggests that the radial stress σ_{r3} due to the couple M may be given by $\sigma_{r3} = -(4/r^2)d'_2 \sin 2\theta$, where d'_2 is a constant, and that the tangential stress $\sigma_{\theta 3} = 0$ everywhere. Equations [1] then give

$$\tau_{r\theta 3} = -\frac{4d'_2}{tr^2}\int t \sin 2\theta \, d\theta + \frac{a'_0}{tr^2}$$

or $$\tau_{r\theta 3} = \frac{4d'_2}{tr^2}\int_{+\theta}^{\alpha_1} t \sin 2\theta \, d\theta + \frac{c}{tr^2}$$

where a'_0 and c are constants. The condition that $\tau_{r\theta 3}$ must equal zero when $\theta = \alpha_1$ requires that $c = 0$, and the condition that $\tau_{r\theta 3}$ must equal zero when $\theta = -\alpha_2$ then requires that

$$\int_{-\alpha_2}^{\alpha_1} t \sin 2\theta \, d\theta = 0 \quad \ldots\ldots [13]$$

This equation is the same as Equations [6] and [11] and hence locates the polar axis in the same position as for a force at the edge of the wedge. Since, from Equation [13]

$$\int_{\theta}^{\alpha_1} t \sin 2\theta \, d\theta = \int_{\theta}^{-\alpha_2} t \sin 2\theta \, d\theta = \int_{\theta}^{\theta_e} t \sin 2\theta \, d\theta$$

where θ_e is either extreme value of θ, that is, either α_1 or $-\alpha_2$ (it is immaterial which), the solution for the wedge loaded by a couple at its edge is of the form

$$\sigma_{r3} = -(4/r^2)d'_2 \sin 2\theta \quad \ldots\ldots [14]$$

$$\sigma_{\theta 3} = 0 \quad \ldots\ldots [15]$$

$$\tau_{r\theta 3} = \frac{4d'_2}{tr^2}\int_{\theta}^{\theta_e} t \sin 2\theta \, d\theta \quad \ldots\ldots [16]$$

The constant d'_2 is most easily determined from the condition of equilibrium of moments. With respect to the edge of the wedge (Fig. 1)

$$\int_{-\alpha}^{\alpha_1} \tau_{r\theta 3} tr^2 d\theta + M = 0$$

that is, $$4d'_2 \int_{-\alpha_2}^{\alpha_1}\int_{\theta}^{\theta_e} t \sin 2\theta \, d\theta \, d\theta + M = 0$$

or, by transforming the integral by integration by parts[5]

$$4d'_2 \int_{-\alpha_2}^{\alpha_1} t\theta \sin 2\theta \, d\theta + M = 0 \quad \ldots\ldots [17]$$

When there is symmetry with respect to a plane bisecting the angle of the wedge, the problem is simplified somewhat: $\alpha_1 = \alpha_2 = \alpha$, and Equations [6], [11], and [13] (all the same equation) drop out.

The Ordinary Theory of Flexure as a Limiting Case of the Theory of the Wedge

The theory that has been presented reduces to the ordinary theory of flexure as α_1 and α_2 approach zero and r becomes infinite. Thus Equation [6] when multiplied by r^2 may be written for small values of θ

$$\int_{-\alpha_2}^{\alpha_1} t\theta r^2 \, d\theta = 0$$

With $z = r\theta$, $z_1 = r\alpha_1$, and $z_2 = r\alpha_2$, this equation becomes

$$\int_{-z_2}^{z_1} tz \, dz = 0$$

that is, the statical moment of the area of the section (now the same as the cross section) with respect to the polar axis (now the neutral surface) must be zero, which is the same thing as saying that the neutral axis passes through the centroid of the cross section. Equation [7], multiplied by r^3, may be written for small values of θ

$$c_1 \int_{-\alpha_2}^{\alpha_1} t\theta^2 r^3 d\theta - P_1 r^3 = 0$$

or $$c_1 \int_{-z_2}^{z_1} tz^2 \, dz - P_1 r^3 = 0$$

The integral in the last equation is the moment of inertia I of the area of the cross section with respect to the neutral axis, and therefore $c_1 = P_1 r^3/I$. Substitution of this value of c_1 in Equation [3] gives, with $z = r\theta$

$$\sigma_{r1} = P_1 rz/I$$

[3] "Plane Strain in a Wedge, With Applications to Masonry Dams," by S. D. Carothers, Proceedings of the Royal Society of Edinburgh, vol 33, 1912–1913, p. 292.

[4] By letting $u = \int_{\theta}^{\theta_e} t \sin 2\theta d\theta$, $dv = d\theta$, as indicated to the author by Dr. G. H. Keulegan.

the stress which would be obtained by the ordinary flexure formula.

Similarly, when θ is small, Equation [11] (same as Equation [6]) indicates that the line of action of P_2 passes through the centroid of the cross section, and Equation [12] when multiplied by r may be written

$$a_1 \int_{-\alpha_2}^{\alpha_1} tr\, d\theta + P_2 r = 0$$

or

$$a_1 \int_{-z_1}^{z_1} t\, dz + P_2 r = 0$$

The integral in the last equation is the area A of the cross section, and thus $a_1 = -P_2 r/A$. Substitution of this value of a_1 in Equation [8] gives for $\theta \approx 0$

$$\sigma_{r2} = -P_2/A$$

the familiar expression for simple tension or compression.

Again, in the case of the couple M Equation [13], being the same as Equations [6] and [11], locates the neutral axis as passing through the centroid of the cross section in the limit $\alpha_1 = 0$, $\alpha_2 = 0$, $r = \infty$. Equation [17] multiplied by r^3 may be written

$$8d'_2 \int_{-\alpha_2}^{\alpha_1} t\theta^2 r^3 d\theta + Mr^3 = 0$$

or

$$8d'_2 \int_{-z_2}^{z_1} tz^2 dz + Mr^3 = 0$$

Since the integral in the last equation is the moment of inertia I of the area of the cross section with respect to the neutral axis

$$d'_2 = -Mr^3/(8I)$$

Substitution of this value of d'_2 in Equations [14] and [16] gives for $\theta \approx 0$, with $z = r\theta$

$$\sigma_{r3} = Mz/I$$

and

$$\tau_{r\theta 3} = -\frac{M}{rIt} \int_z^{z_2} tz\, dz$$

The expression for σ_{r3} is again the ordinary flexure formula, and the expression for $\tau_{r\theta 3}$ is the one which would commonly be used in an ordinary beam subjected to a finite shearing force M/r at the cross section in question. If M is finite and $r = \infty$, $\tau_{r\theta 3} = 0$.

The Theory of the Wedge and the Ordinary Theory Applied to a Plate Girder With Nonparallel Flanges

Some idea of the magnitude of the error involved in using the ordinary theory instead of the theory of the wedge may be obtained by comparing the maximum fiber stresses computed by both theories in the case of a plate girder which is triangular (or trapezoidal) in elevation and symmetrical with respect to the line bisecting the angle between the flanges, $\alpha_1 = \alpha_2 = \alpha$. The cross-sectional area of each flange is assumed to be constant and concentrated at its centroid in order to simplify the computation.

The stress σ_{r1} along a circular-cylindrical section A-A in Fig. 1, due to a force P_1 at the intersection of the flanges (or the flanges extended) is obtained by determining the constant c_1 from Equation [7] and inserting its value in Equation [3]. Equation [7] becomes in the present case

$$2c_1 \frac{A_f}{r} \sin^2 \alpha + c_1 t \int_{-\alpha}^{\alpha} \sin^2 \theta\, d\theta - P_1 = 0$$

where A_f is the cross-sectional area of one flange and t is the thickness of the web. This equation solved for c_1 gives

$$c_1 = \frac{P_1 r}{tr(\alpha - \sin \alpha \cos \alpha) + 2A_f \sin^2 \alpha}$$

and this value of c_1 inserted in Equation [3] gives

$$\sigma_{r1} = \frac{P_1 \sin \theta}{tr\,(\alpha - \sin \alpha \cos \alpha) + 2\,A_f \sin^2 \alpha} \qquad [18]$$

which is a maximum, at A Fig. 1, when $\theta = \alpha$

$$\sigma_{r1\max} = \frac{P_1 \sin \alpha}{tr\,(\alpha - \sin \alpha \cos \alpha) + 2A_f \sin^2 \alpha}$$

According to the ordinary beam theory the maximum fiber stress f_1 on a cross section, A-A in Fig. 1, due to the force P_1 occurs at A and is

$$f_1 = \frac{P_1 r \cos \alpha \cdot r \sin \alpha}{(2/3)tr^3 \sin^3 \alpha + 2A_f \sec \alpha \cdot r^2 \sin^2 \alpha}$$

$$= \frac{P_1 \cos \alpha}{(2/3)tr \sin^2 \alpha + 2A_f \tan \alpha}$$

The ratio of f_1 to $\sigma_{r1\max}$ is

$$\frac{f_1}{\sigma_{r1\max}} = \frac{\cos^2 \alpha \left(\dfrac{\alpha - \sin \alpha \cos \alpha}{2\alpha \sin^2 \alpha} + \dfrac{A_f}{tr\alpha} \right)}{\dfrac{\sin \alpha \cos \alpha}{3\alpha} + \dfrac{A_f}{tr\alpha}}$$

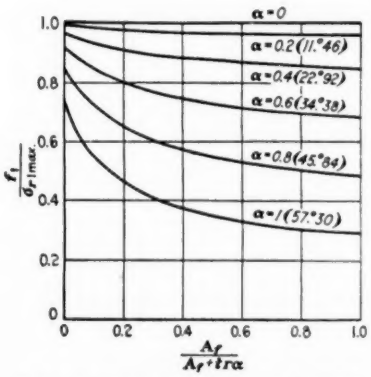

FIG. 2 CANTILEVER-LOADING CURVES

(Showing ratio of maximum fiber stress by the ordinary beam theory to maximum fiber stress by the wedge theory for all values of ratio of flange area to total circular-cylindrical-sectional area and for different values of the half angle of a wedge-shaped plate girder loaded as a cantilever.)

This ratio is shown in Fig. 2 for various values of α and for all possible values of the ratio $A_f/(A_f + tr\alpha)$ of the circular-cylindrical-sectional area of the flanges to the total circular-cylindrical-sectional area.

The stress σ_{r2} along a circular-cylindrical section A-A in Fig. 1, due to a force P_2 at the intersection of the flanges (or the flanges extended) is obtained by determining the constant a_1 from Equation [12] and inserting its value in Equation [8]. Equation [12] becomes in the present case

$$2a_1 \frac{A_f}{r} \cos^2 \alpha + a_1 t \int_{-\alpha}^{\alpha} \cos^2 \theta\, d\theta + P_2 = 0$$

from which

$$a_1 = -\frac{P_2 r}{tr(\alpha + \sin \alpha \cos \alpha) + 2A_f \cos^2 \alpha}$$

This value of a_1 inserted in Equation [8] gives

$$\sigma_{r2} = -\frac{P_2 \cos\theta}{tr(\alpha + \sin\alpha\cos\alpha) + 2A_f\cos^2\alpha} \quad \ldots\ldots [19]$$

which is a (numerical) maximum at the polar axis $\theta = 0$ so that

$$\sigma_{r2max} = -\frac{P_2}{tr(\alpha + \sin\alpha\cos\alpha) + 2A_f\cos^2\alpha}$$

By elementary methods the stress f_2 on a cross section through the same point (the intersection of the polar axis and the arc A-A in Fig. 1) due to the force P_2 would be computed as

$$f_2 = -\frac{P_2}{2tr\tan\alpha + 2A_f\sec\alpha}$$

The ratio of f_2 to σ_{r2max} is

$$\frac{f_2}{\sigma_{r2max}} = \frac{\cos^3\alpha\left(\dfrac{\alpha + \sin\alpha\cos\alpha}{2\alpha\cos^2\alpha} + \dfrac{A_f}{tr\alpha}\right)}{\dfrac{\sin\alpha}{\alpha} + \dfrac{A_f}{tr\alpha}}$$

This ratio is shown in Fig. 3 for various values of α and for all possible values of the ratio $A_f/(A_f + tr\alpha)$.

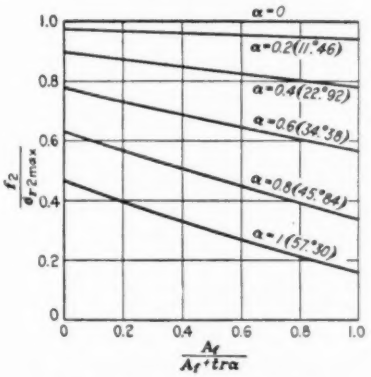

FIG. 3 AXIAL-LOADING CURVES

(Showing ratio of maximum stress by the ordinary prism theory to maximum stress by the wedge theory for all values of ratio of flange area to total circular-cylindrical-sectional area and for different values of the half angle of a wedge-shaped plate girder loaded axially.)

The stresses σ_{r3} and $\tau_{r\theta3}$ along a circular-cylindrical section, A-A in Fig. 1, due to a couple M at the intersection of the flanges (or the flanges extended) are obtained by determining the constant d'_2 from Equation [17] and inserting its value in Equations [14] and [16]. Equation [17] becomes in the present case

$$8d'_2\frac{A_f}{r}\alpha\sin 2\alpha + 4d'_2t\int_{-\alpha}^{\alpha}\theta\sin 2\theta\,d\theta + M = 0$$

from which

$$d'_2 = -\frac{Mr}{2[tr(\sin 2\alpha - 2\alpha\cos 2\alpha) + 4A_f\alpha\sin 2\alpha]}$$

This value of d'_2 inserted in Equation [14] gives

$$\sigma_{r3} = \frac{2M\sin 2\theta}{r[tr(\sin 2\alpha - 2\alpha\cos 2\alpha) + 4A_f\alpha\sin 2\alpha]} \quad \ldots [20]$$

When $\alpha \leqq \pi/4$, σ_{r3} is a maximum at A, Fig. 1, $\theta = \alpha$, and

$$\sigma_{r3max} = \frac{2M}{r[tr(1 - 2\alpha\cot 2\alpha) + 4A_f\alpha]}$$

If $\alpha \geqq \pi/4$, σ_{r3} is a maximum at $\theta = \pi/4$ and is given by setting $\sin 2\theta = 1$ in Equation [20].

According to the ordinary beam theory the maximum fiber stress f_3 on a cross section A-A, Fig. 1, due to a couple M occurs at A and is

$$f_3 = \frac{Mr\sin\alpha}{(2/3)tr^3\sin^3\alpha + 2A_f\sec\alpha\cdot r^2\sin^2\alpha} = \frac{M}{2r[(1/3)tr\sin^2\alpha + A_f\tan\alpha]}$$

The ratio of f_3 to σ_{r3max} for $\alpha \leqq \pi/4$ is

$$\frac{f_3}{\sigma_{r3max}} = \frac{\alpha\cot\alpha\left[\dfrac{1}{4\alpha^2}(1 - 2\alpha\cot 2\alpha) + \dfrac{A_f}{tr\alpha}\right]}{\dfrac{\sin\alpha\cos\alpha}{3\alpha} + \dfrac{A_f}{tr\alpha}}$$

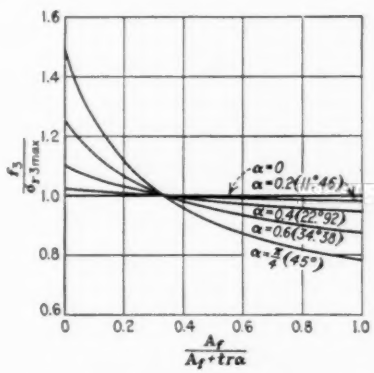

FIG. 4 COUPLE-LOADING CURVES

(Showing ratio of maximum stress by the ordinary beam theory to maximum stress by the wedge theory for all values of ratio of flange area to total circular-cylindrical-sectional area and for different values of the half angle of a wedge-shaped plate girder loaded by a couple at the edge end.)

This ratio is shown in Fig. 4 for various values of α and for all possible values of the ratio $A_f/(A_f + tr\alpha)$.

Inspection of Figs. 2, 3, and 4 shows that so long as the included angle of the wedge does not exceed 20 deg ($\alpha = 10$ deg) the ordinary beam theory will never be in error on the unsafe side by more than about 5 per cent nor on the safe side by more than about 2 per cent. For larger angles the error may increase rapidly with the angle, however.

In order to obtain $\tau_{r\theta3}$ in a useful form, it is necessary to evaluate the integral in Equation [16]. In the present case one obtains

$$\int_{\theta}^{\theta_e} t\sin 2\theta\,d\theta = \frac{A_f}{r}\sin 2\alpha + t\int_{\theta}^{\alpha}\sin 2\theta\,d\theta = (A_f/r)\sin 2\alpha - (t/2)(\cos 2\alpha - \cos 2\theta)$$

and insertion of this value of the integral and the previously found value of d'_2 in Equation [16] gives

$$\tau_{r\theta3} = -\frac{M[tr(\cos 2\theta - \cos 2\alpha) + 2A_f\sin 2\alpha]}{tr^2[tr(\sin 2\alpha - 2\alpha\cos 2\alpha) + 4A_f\alpha\sin 2\alpha]} \quad \ldots [21]$$

which is a (numerical) maximum at the polar axis $\theta = 0$ so that

$$\tau_{r\theta3max} = -\frac{M[tr(\csc 2\alpha - \cot 2\alpha) + 2A_f]}{tr^2[tr(1 - 2\alpha\cot 2\alpha) + 4A_f\alpha]}$$

In the case of pure bending by a couple M if the ordinary beam theory were used, the corresponding shearing stress would be zero.

Curved Extreme Fibers

The theory may be applied as an approximation to beams having curved extreme fibers. In such a case a wedge may be formed for analytical purposes by first drawing a tangent to the extreme fiber at any point and then swinging an arc through this point with center on the tangent and with such a radius that it intersects the opposite extreme fiber at right angles. The tangents from the center of this arc to the extreme fibers, together with the arc, form a wedge and the stresses along the arc (circular-cylindrical section) may be computed by the theory which has been presented. It is to be expected in the case of curved extreme fibers that the theory will give better values, the smaller the curvature.

An example of this kind will be given in which the theory was substantiated by actual determination of stresses from strains measured on a rigid-frame specimen with curved inner flange. This specimen was tested recently at the National Bureau of Standards.[2] One half of the specimen is shown in

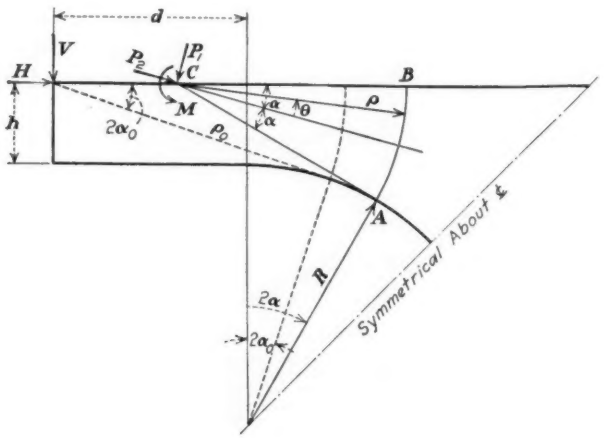

Fig. 5 Outline of One Half of a Rigid-Frame Specimen With Curved Inner Flange

outline in Fig. 5 and the entire specimen is shown in Fig. 6. The flange (indicated by heavy lines in Fig. 5) consisted of two $4 \times 4 \times {}^1/_2$-in. angles, and the web plate was ${}^3/_8$ in. thick. The distance h between the centroids of the cross-sectional areas of the flanges was 15.7 in., the distance d from the point of application of the load to the point of tangency of the curved part of the inner flange with the straight part was 49.85 in., and the radius R of the centroidal line of the curved inner flange was 61.15 in.

In order to determine the state of stress in the specimen, tangents were drawn from several points, such as A in Fig. 5, on the

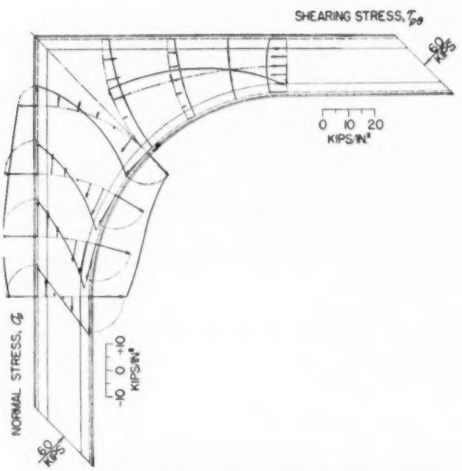

Fig. 6 Rigid-Frame Specimen With Curved Inner Flange
(One kip equals 1000 lb.)

curved inner flange intersecting the straight outer flange, as at C. With these points of intersection as centers, arcs such as AB were swung through the points of tangency. The stresses along these arcs of radius ρ and included angle 2α could then be determined from Equations [18], [19], [20], and [21] by inserting the values of $r = \rho$ and the proper values of P_1, P_2, and M. These quantities in terms of the components H and V of the applied load and the other known quantities are easily found to be

$$\rho = \frac{h + R(1 - \cos 2\alpha)}{\sin 2\alpha}$$

$$P_1 = V \cos \alpha - H \sin \alpha$$

$$P_2 = V \sin \alpha + H \cos \alpha$$

$$M = V\left[d - \frac{h \cos 2\alpha - R(1 - \cos 2\alpha)}{\sin 2\alpha}\right]$$

The dotted lines in Fig. 5 indicate the wedge (included angle $2\alpha_0$, radius ρ_0) for which $M = 0$. Along the dotted arc $2\rho_0\alpha_0$ the shearing stresses are everywhere zero, and at the extremities of this convenient arc the normal stresses are nearly a maximum. For a detailed discussion the reader is referred to the paper cited in footnote 2.

Fig. 6 shows by means of curves at various circular-cylindrical sections the theoretical stresses on these sections and also by means of arrows the stresses which were determined from measurements of strain under a 60,000-lb load applied as indicated. It is considered that the agreement is within the experimental error.

Design Data

It is important that the data contained in technical papers be made readily available to designing engineers. In order to satisfy these needs of industry, this section of the JOURNAL will include a concise presentation of data and information drawn chiefly from papers previously published by the Applied Mechanics Division of The American Society of Mechanical Engineers.

The first series dealt with the subject "Strength of Materials" and the present series will cover the subject "Vibration." The data have been prepared by a subcommittee of the Applied Mechanics Division (J. Ormondroyd, chairman), under the general guidance of S. Timoshenko.

The second article, which follows, is by J. Ormondroyd. This considers the dynamic specifications of a system and there is included a table of typical spring constants both linear and torsional.

Vibration Problems

PART II

BY J. ORMONDROYD,[1] ANN ARBOR, MICH.

THE major part of any vibration analysis lies in the calculation of the dynamic specifications of the simplified system which represents the machine or structure being studied. The dynamic specifications of a system are the numerical values of the masses, moments of inertia, spring constants, and damping constants which determine its dynamic behavior. These quantities are the coefficients which appear in the differential equations of motion of the system.

DYNAMIC SPECIFICATIONS

Mass.

The calculation of mass requires little comment except that the value of g used in the lb-in-sec system is 386 in./sec^2. In the lb-mass-ft-sec system the unit of mass is the slug; 1 slug weighs 32.2 lb, 1 lb mass weighs 1 lb. The unit of mass in the lb-in-sec system has no official name. For engineers it is always safest to forget the named units of mass and name the mass units after the units of w/g, that is, lb sec^2/in. (g = 386 in. sec^2) or lb sec^2/ft (g = 32.2 ft/sec^2).

For bodies of simple shape and uniform material

$$m = \gamma V/g \text{ lb sec}^2/\text{in.}$$

where γ = weight per cubic inch
V = volume in cubic inches
g = acceleration of gravity, in./sec^2

In many cases actual weights W can be measured, in which case

$$m = W/g \text{ lb sec}^2/\text{in.}$$

Moments of Inertia.

Methods of calculating moments of inertia are given in most treatises on mechanics and in all handbooks. A complete and understandable treatment of the analytical method of calculating moments of inertia is given by Timoshenko and Young (1).[2] Condensed treatments of the subject are given in Marks' Handbook (2) and Eshbach's Handbook (3).

Tables of mass moments of inertia for bodies of simple shapes are given by Timoshenko and Young (4), Marks (5), and Eshbach (6).

In American engineering practice three totally different quantities are designated by the single term "moment of inertia." In calculating the deflections of beams a geometrical moment of inertia of the beam cross-sectional area taken with respect to the neutral axis is used. This has *in.*^{4} units. For twisted beams a geometrical polar moment of inertia of the beam cross section taken with respect to the axis of twist is used. This also has *in.*^{4} units. The mass moment of inertia taken with respect to the axis of rotation is defined by the equation $I = \int r^2\, dm$ and has the units *lb in. sec*^{2}. All three are usually discussed together. The engineer must be careful to select the right kind for the problem he has at hand.

Although the geometrical moments of inertia must not be confused with the mass moments of inertia, a simple relationship does exist between the geometrical polar moment of inertia J of the cross section around the axis of rotation and I the mass moment of inertia around the same axis. For bodies of constant axial thickness

$$I = J \times \frac{\text{total mass}}{\text{cross-sectional area}} \text{ lb in. sec}^2$$

Some of the older handbooks define moment of inertia in Wr^2 (weight × length squared) units. This is sometimes called "flywheel effect." The flywheel effect divided by g (the acceleration of gravity) is the mass moment of inertia as used in these articles.

Moments of inertia can be measured if the body in question can be suspended as a pendulum and set into oscillation.

$$I = \frac{WlT^2}{4\pi^2} \text{ and } I_0 = Wl\left(\frac{T^2}{4\pi^2} - \frac{l}{g}\right)$$

where
W = weight, in pounds, found by weighing
l = shortest distance from axis of rotation to center of gravity, found by measurement
T = period of pendulum in seconds, measured experimentally

Spring Constants.

The spring constants of the various types of elastic members which occur in machines and structures can be calculated by

[1] Professor of Engineering Mechanics, University of Michigan. Mem. A.S.M.E.

[2] Numbers in parentheses refer to the Bibliography.

methods developed in the theory of elasticity. The sections of this theory which deal with the deflections and deformations of bodies and groups of connected bodies under the action of various types of loading can be used directly to indicate methods of spring-constant calculation.

Tables of linear and torsional deflections of beams under loads and twisting moments are given in all handbooks. These can be used to calculate the spring constants, since these are the load divided by the deflection. Fundamental methods for calculating deflections of beams and structures in bending are given by Timoshenko and Lessells (7) and by Timoshenko (8). Torsional-deflection calculations are discussed by Timoshenko and Lessells (9) and by Timoshenko (10).

Methods using *strain energy* are very important practically. These methods are discussed by Timoshenko and Lessells (11), Timoshenko (12), and Van den Broek (13).

Timoshenko and Lessells (14) give a very detailed discussion of the axial and bending deflection of helical springs with large pitch angle in which the energy method is used.

Graphical methods become necessary when beams with many concentrated loads, many changes in cross-sectional dimension, and irregularly distributed loadings are under investigation. This method is discussed by Timoshenko and Lessells (15).

For many torsional-deflection problems, Prandtl's Membrane Analogy gives the only easily attainable results. This method is outlined by Timoshenko and Lessells (16) and by Timoshenko (17).

Grammel (18) gives a method for treating helical springs as solid beams for compression, tension, bending, and twisting.

Tables which give deflections of beams under various loadings can often be used to calculate spring constants. Such tables for bending are given in Marks' Handbook (19) and Eshbach's Handbook (20); and for twisting, Marks' Handbook (21) and Eshbach's Handbook (22). Marks' Handbook (23) gives the deflection of many types of springs in a separate section.

On the last page of this contribution 24 typical spring constants are given. In reading the table, it should be kept in mind that the spring constants are defined as ratios. The linear constant $k_l = P/\Delta$; P = load or force causing the deflection, Δ = the deflection in the direction of the load causing it at the point of application of the load. The torsional constant $K_t = M/\varphi$; M = the twisting moment causing the angular distortion. It acts in a plane perpendicular to the axis of twist; φ = the angular deflection around the axis of twist in the plane of the twisting moment. The torsional constant in bending $K_{tb} = M/\varphi$; M = bending moment acting on the beam, φ = the angle between the tangents to the neutral axis of the beam in the plane of the bending moment before and after the moment is applied.

It should be remembered that in unsymmetrical structures or in symmetrical structures unsymmetrically loaded, other deformations beside the ones which appear in the spring constants can occur. The point of application of the load may deflect at right angles to the load. Rotations around the point of application of the load may also occur. In many simple problems these additional distortions may be ignored—in a more refined analysis they would have to be considered.

Damping Constants.

Damping or friction forces are always associated with the energy losses of the system. Whenever the macroscopic or molar motion of the system is transformed into microscopic or molecular motion in the bodies of the system itself, or in the medium which surrounds the body, damping exists. Most generally stated, damping forces exist when momentum is transferred from the vibrating system to the rest of the universe which is not included in the system isolated for study. Naturally transfer of molar momentum to other macroscopic bodies in the same system is not considered as damping.

Two general types of damping forces exist—friction forces and impactive forces. Friction forces occur between the surfaces of bodies moving relatively to each other. They are tangential to the surfaces at the points of action, they are functions of velocity and always act in the opposite direction to the velocity. Friction forces occur internally between the particles which form the body as well as on its outer surface. Impactive forces occur whenever the moving body sets the surrounding medium in motion, whether this medium be fluid or solid.

A complete discussion of the various types of damping forces is given by Stanton (24). A very general paper considering damping as specifically applying to vibrating systems was written by Kimball (25).

Coulomb Friction.

The kinetic or sliding Coulomb friction force is $F = \pm \mu N$, where μ is a coefficient of friction and N is the normal force exerted on the moving bodies by the surrounding bodies which touch it and to which it is moving relatively. Extensive references to this type of damping are given by Timoshenko (26). Tables of values for kinetic or sliding friction between several materials are given in Marks' Handbook (27) and Eshbach's Handbook (28). Free and forced vibration of systems of one degree of freedom on which Coulomb friction is acting are discussed by Timoshenko (29) and Den Hartog (30). Den Hartog (31) has also given a rigorous solution for this problem. Kimball (25) has discussed an energy method for dealing with this type of vibration damping and Jacobsen (32) has given a valuable approximate method for forced vibration with Coulomb damping.

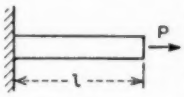
Internal Friction in Solids.

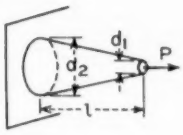
No accurate and simple detailed description of internal hysteresis forces has yet been made. They are usually handled quantitatively by experiments which give the energy lost per cycle of distortion as a function of the maximum stress occurring during the cycle of motion. Kimball (25) has treated this subject. Kimball and Lovell (33) have described an ingenious experiment in which the internal hysteresis of materials in tension and compression can be measured. Rowett (34) and Föppl (35) have made investigations of hysteresis losses in metals in torsion.

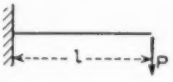
Viscous Friction.

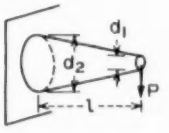
Viscous friction occurs at lubricated surfaces and on the surfaces of bodies moving slowly through gaseous and fluid media. The whole theory of viscous friction stems from the simple definition proposed originally by Newton and put into its modern form by Maxwell

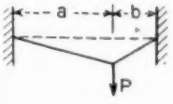
$$F = -\eta A v/h$$

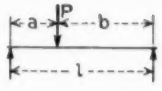


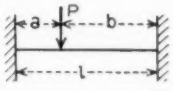


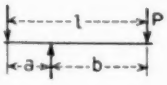


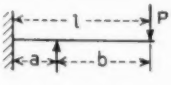


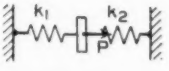


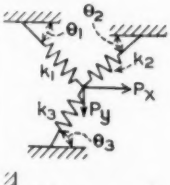


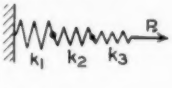








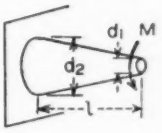


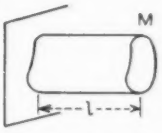


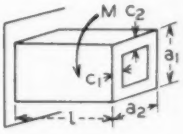
Here η is the coefficient of viscosity of the fluid involved, A is the area of the surface in contact with the fluid, h is the thickness of the lubricating fluid between the bodies in relative motion and v is the relative velocity of the two contiguous surfaces.

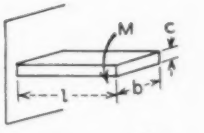
Viscous friction is discussed extensively in all treatises on hydrodynamics. Stanton (24) devotes a large section of his book to its discussion. This type of friction lends itself to convenient mathematical manipulation. For this reason nearly all theoretical investigations on vibration assume it to be the only friction existing. This is equivalent to assuming that all types of damping can be described by an equivalent viscous damping. Jacobsen (32) has indicated that this assumption is practically substantiated.

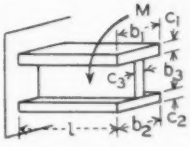
Impactive Damping.

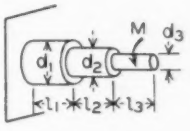












Impactive damping forces are described by simple equations

LINEAR SPRING CONSTANTS

	DESCRIPTION	SPRING CONSTANT LB PER IN.
	BARS OF CONSTANT CROSS SECTION IN TENSION OR COMPRESSION E = MODULUS OF ELASTICITY, LB PER SQ IN. A = CROSS-SECTIONAL AREA, SQ IN. l = LENGTH	$\frac{EA}{l}$
	TRUNCATED CONE IN TENSION OR COMPRESSION	$\frac{\pi d_1 d_2}{4}\ \frac{E}{l}$
	CANTILEVER BEAM, CONSTANT SECTION, LOADED AT FREE END	$\frac{3EI}{l^3}$
	TAPERED CONE, AS CANTILEVER BEAM LOADED ON FREE END	$\frac{3E}{l^3}\ \frac{\pi d_2^4}{64}\ \frac{d_1}{d_2}$
	SMALL LATERAL DEFLECTIONS OF STRETCHED ELASTIC STRING T = ORIGINAL TENSION FORCE IN THE STRING	$T\ \frac{a+b}{ab}$
	SIMPLY SUPPORTED BEAM, CONSTANT CROSS SECTION	$\frac{3EI}{l^3}\ \frac{(a+b)^4}{a^2b^2}$
	CONSTANT CROSS SECTION, BEAM BUILT IN AT BOTH ENDS	$\frac{3EI}{l^3}\cdot\frac{l^2}{a^3b^3}$
	SPRINGBOARD BEAM, CONSTANT CROSS SECTION	$\frac{3EI}{l(l-a)^2}$
	SPRINGBOARD BEAM BUILT IN AT ONE END	$\frac{3EI}{l(l-a)^2\left(1-\frac{1}{4}\frac{a}{l}\right)}$
	SPRINGS IN PARALLEL	$k_1 + k_2$
	A GROUP OF STRETCHED SPRINGS ATTACHED TO ONE CENTER. θ_n IS THE SMALLEST ANGLE EACH SPRING MAKES WITH THE HORIZONTAL AT EQUILIBRIUM BEFORE LOADING	$k_x = \sum k_n \cos^2\theta_n$ $k_y = \sum k_n \sin^2\theta_n$
	SPRINGS IN SERIES	$k = \frac{1}{\frac{1}{k_1}+\frac{1}{k_2}+\frac{1}{k_3}}$
	FOR m SPRINGS IN SERIES	$k = \frac{1}{\sum_{n=1}^{n=m}\frac{1}{k_n}}$

TORSIONAL SPRING CONSTANTS

ROTATIONS CAUSED BY TWISTING MOMENTS

	DESCRIPTION	SPRING CONSTANT LB-IN. PER RADIAN
	TRUNCATED CONE G=MODULUS OF ELASTICITY IN SHEAR	$\frac{G}{32l}\ \frac{\pi(d_2-d_1)d_1^3 d_2^3}{d_2^3-d_1^3}$
	PRISM, CONSTANT CROSS SECTION OF SIMPLE OR IRREGULAR SHAPE. NO HOLES IN CROSS SECTION. A = AREA OF CROSS SECTION J = POLAR MOMENT OF INERTIA OF CROSS SECTION (ST. VENANT'S ELLIPTIC SECTION GOOD APPROXIMATION FOR ALL SECTIONS)	$\frac{G}{l}\ \frac{A^4}{4\pi^2 J}$
	RECTANGULAR HOLLOW TUBE	$\frac{G}{l}\ \frac{2}{\frac{1}{a_1 a_2^2 c_1}+\frac{1}{a_1^2 a_2 c_2}}$
	RECTANGULAR-CROSS-SECTION BAR	$\frac{G}{l}\ \frac{bc^3}{3}$
	I-BEAM	$\frac{G}{l}\ \frac{\sum b_n c_n^3}{3}$
	TORSIONAL SPRINGS IN SERIES	$k = \frac{\pi G}{32}\ \frac{1}{\sum_{n=1}^{n=m}\frac{l_n}{d_n^4}}$

ROTATIONS CAUSED BY BENDING MOMENTS

	CANTILEVER BEAM, CONSTANT CROSS SECTION	$\frac{EI}{l}$
	SIMPLY SUPPORTED BEAM, ROTATION AT POINT OF APPLICATION OF MOMENT	$\frac{3EI}{l}\ \frac{1}{1-\frac{3ab}{l^2}}$
	BEAM BUILT IN AT BOTH ENDS	$\frac{6EI}{l}\ \frac{(l+b)l^4}{9a^2b^3+abl^2(12b-3a)}$
	FLYWHEEL SPOKES, CONSTANT CROSS SECTION n = NUMBER OF SPOKES r = LENGTH OF SPOKES	$n\frac{4EI}{r}$
	EQUIVALENT TORSIONAL-SPRING CONSTANT OF LINEAR SPRINGS AROUND AXIS A	$\sum k_n r_n^2$

of the type $F = Cv^n$, where $n \geq 2$. In ordinary vibration problems perhaps only the case in which $n = 2$, velocity-squared damping, has any importance. This damping occurs when the vibrating bodies have high velocities in a fluid or gaseous medium. The term "high velocity" here has meaning only in terms of the Reynolds number which exists for the particular case. Wherever waves and eddies are created by the vibrating body in the medium surrounding it, damping proportional to v^2 can be assumed to exist. This probably holds true, at least approximately, even in the case where the vibration is limited to impact with solid bodies. Hort (36) discusses free vibrations with velocity-squared damping and Forchheimer (37) gives a more extensive treatment to the subject. Forced vibrations with velocity-squared damping can be treated by Jacobsen's (32) energy method.

Discussion

Methods of Rotor-Unbalance Determination[1]

T. C. Rathbone.[2] Developments of methods for balancing turbine-generator installations under operating conditions became necessary, since the slow-speed dynamic-balancing machine correction at room temperature in the factory does not assure satisfactory operation.

The field-balancing methods are based on vibration observations at the bearings, which include determination of both the amplitude and the phase relation between vibratory motion and the angular rotor position, in other words, the "vibration vector." The change in the initial vectors brought about by the addition of a known unit of unbalance in a known position determines the "unit vectors" for all bearings, resulting from the unit of unbalance at the location applied.

With the assumption of linearity, these groups of unit vectors, defining the response of all bearings produced by unit unbalance at each corrector location, determine a fixed characteristic of the installation. Once evaluated, any unknown unbalance can then be corrected by canceling its vectors with appropriate adjustment of the unit vectors.

In the writer's paper,[3] a graphic solution by trial was described for the two-bearing case, also a rough method by inspection indicated for the four-bearing case. E. L. Thearle[4] described an analytical method for the final step, which yields a direct solution for the two-bearing case. F. C. Rushing and B. A. Rose[5] proposed another vectorial-operation method for the solution of the two-bearing case.

The author points out that the previous analytical methods are cumbersome and, under certain conditions, lead to large errors. This is particularly true, where the response at a distant bearing is large in relation to the effect at a bearing nearest the corrector application or, where differences between large quantities are handled. His experience has also been that frequently the desired correction is not obtained at once and additional trials are necessary for further reduction of the residual. He proposes an intermediate step using groups of trial weights, selected so that their effect is nil at all but the bearing selected for observation, and develops expressions involving vector quantities for this determination for both the two- and the three-bearing case. The residual or remnant errors then rapidly converge for elimination within the tolerance. The author's analytical and instrumentation contributions in balancing have been outstanding.

The writer has preferred the purely graphic handling of the vector solutions, as being simpler and more easily followed by the practical engineer. Since the original paper he also has extended the graphic method to take advantage of the reduction in graphic trials afforded by adopting combinations or groups of trial weights which affect only the selected bearing.

The method of using combinations of weights was suggested by the analogy with the Marsland process,[6] used with the Westinghouse dynamic-balancing machine, in which pairs of corrector weights are computed, which affect one end only without upsetting the balance at the other end.

The case of the two-bearing rotor is shown in Fig. 8, where A and B are the unit trial weights and the following numerical values are assumed:

$1A$ is the unit vibration vector at bearing No. 1 due to unit weight A
$2A$ is the unit vibration vector at bearing No. 2 due to unit weight A
$1B$ is the unit vibration vector at bearing No. 1 due to unit weight B
$2B$ is the unit vibration vector at bearing No. 2 due to unit weight B

These unit vectors have been determined by observations on the two bearings for the initial condition with unknown unbalance as found, and on the two trial runs with the trial weight first at A and then at B. The unit vectors are the closing vectors between the initial condition as found and the condition as altered by the application of the unit trial weights.

It is required to replace the unit trial weight A by a combination of A and a weight b at the other end, such that the vector at the No. 2 bearing is nil. Unit weight A produces a secondary

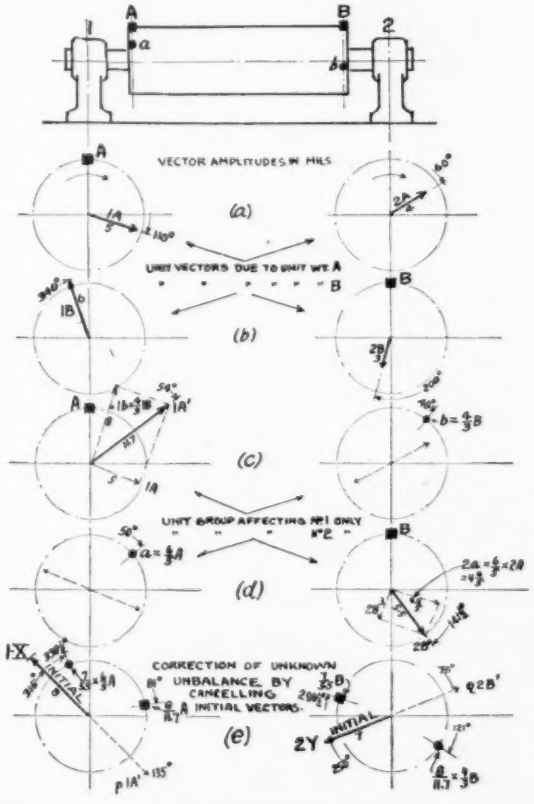

Fig. 1 Graphic Method Employing Groups of Trial Weights Applied to Two-Bearing Rotor

vector $2A$ at the No. 2 bearing. A weight b is selected whose magnitude is in the ratio of the magnitude of the vectors $2A$ and $2B$, and whose angular position is such that the vectors cancel. The amount and location is represented by b, Fig. 1(c).

However, the addition of unit b produces a secondary vector at the No. 1 bearing, in the same relation that B produces the vector $1B$. Call this secondary vector $1b$. The vectorial sum of $1A$ and $1b$ is $1A'$. Thus, for the unit trial combination of A and b, the unit vector is $1A'$ at the No. 1 bearing, and zero at the No. 2 bearing. By the same process, the combination of trial weight B and a produces a zero vector at the No. 1 bearing and unit vector $2B'$ at the No. 2 bearing, Fig. 1(d).

These single-unit vectors can now be applied directly to nullify the initial vectors due to the initial unbalance. Thus, if in Fig. 1(e) $1X$ and $2Y$ are the original unknown unbalance vectors, the adjusted-unit groups are found directly, whose vectors $p1A'$ and $q2B'$ are equal and opposite, canceling the originals. In practice, the two corrector weights at each end are combined into single weights for final application to the rotor.

The three and four-bearing installations are of course more difficult to solve graphically, than the two-bearing case, but the labor is still entirely graphical. In Fig. 2 the usual four-bearing set is illustrated, each rotor having two corrector planes, and ignoring for the time the corrector zones now commonly provided along the body of long, flexible rotors.

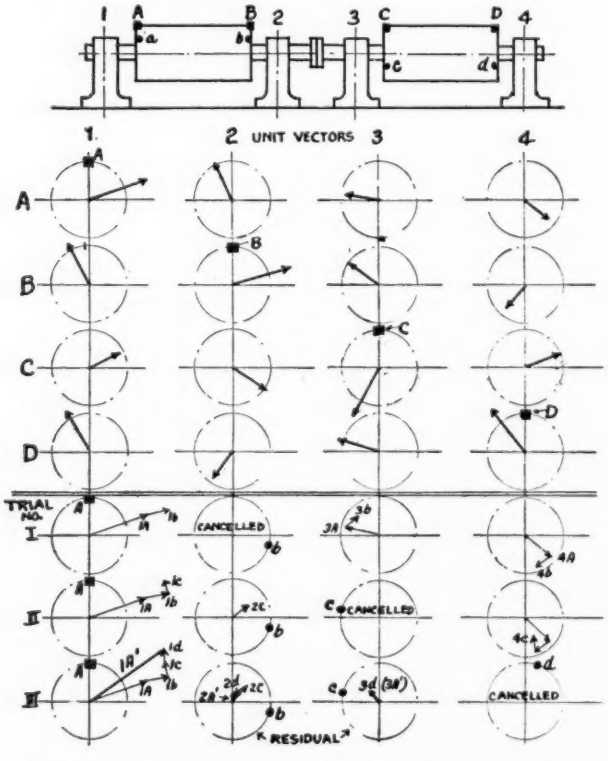

FIG. 2 UNIT WEIGHT GROUP TO AFFECT NO. 1 BEARING ONLY
(Residual reduced by continuing trial process; groups for other bearings found in similar manner.)

The four-bearing case involves sixteen vectors, evaluated by four trial runs with the unit weight in each of the locations. The direct application of these vectors for correction of the initial unbalance, even by the graphic process, would be difficult. However, if these data are reduced to unit groups affecting one bearing only, with zero vectors at all other bearings, the problem becomes simple, as the author points out.

In Fig. 2, the graphic trial process is indicated for determining the weight groups which will produce a "primary" vector at the No. 1 bearing, with zero or insignificant residual vectors at the other three bearings. The vectors at Nos. 2, 3, and 4 due to A are canceled in turn by appropriate adjustment of amount and angular position of units B, C, and D. This is accomplished with merely a protractor and simple arithmetic. A primary vector is left at No. 1, secondary residuals at Nos. 2 and 3, and zero at No. 4. If the residuals at Nos. 2 and 3 are still significant, the process is repeated until they are less than one third of the permissible tolerance. If the response from a weight is greater at a distant than at a nearer bearing, an inversion is necessary for convergence.

In like manner, unit groups are found which produce a primary vector at Nos. 2, 3, and 4, respectively, and zero at the other bearings. These unit groups can now be applied directly to cancel the initial unbalance vectors graphically. The four weights resulting at each location would in practice be combined into single corrector weights for actual application to the job. The most unfavorable sum of the residuals would still be within the tolerance.

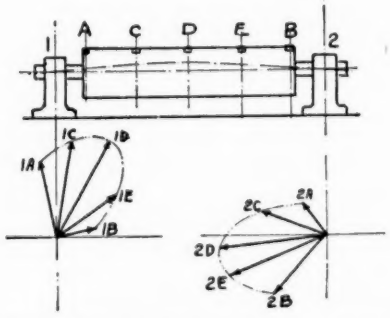

FIG. 3 TRIAL RUNS ON A FLEXIBLE ROTOR

The Vectorscope,[7] described by G. J. Dashefsky, developed to aid in the analysis of Diesel-engine balancing and torsional vibration, would seem to have application to the present problem. Four Vectorscopes, geared together with means for altering the vectors proportionately, would aid in determining the necessary trial group combinations.

The balancing of large rotors in service is not a mass-production procedure. There is usually ample time between runs for the graphic work which should greatly reduce the number of shutdowns.

During the meeting, the author pointed out some situations which introduced nonlinearity between cause and effect. One of the conditions, which brings about nonlinear vector response, arises when the trial-unbalance location is shifted axially on long flexible rotors. From the flexural consideration, a given unit of unbalance produces the greatest mass displacement and hence disturbance, when located midway between the bearings.

In Fig. 3, representing trial runs on a flexible rotor, the vibratory responses for a unit of unbalance at various axial locations would be expected to appear as indicated by the vectors. The vectors at Nos. 1 and 2 bearings are represented by $1A$ and $2A$, respectively, for the weight located at A, and so on. The magnitudes increase as the unit weight approaches the mid-position.

If this relationship were established by actual trial, it might be useful for computing the transfer of corrections from the ends to the middle body, except for the fact, which the author cited, that the particular mode of vibration may introduce a complication.

[7] "The Vectorscope," by G. J. Dashefsky, Trans. A.S.M.E., vol. 61, July, 1939, p. 403.

If the rotor and its elastic supporting structure are vibrating in the mode with the pedestals in phase, Fig. 4(*a*), the flexural relationship may hold. If a resonant condition is approached, in the "seesaw" mode with the pedestals moving in opposite phase, as indicated in Fig. 4(*b*) the unbalance at the node at the middle is not as effective as at the rotor ends.

The flexural condition might be tested by making a trial run with a unit weight at the center, as at *W*, Fig. 4 (*a*) and two equal weights of $^1/_2$ *W* at the ends, in the opposite direction. As these weights constitute a dynamically balanced system, the

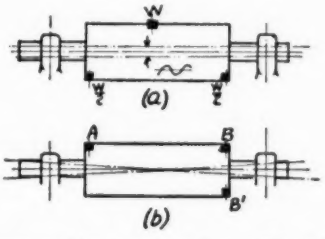

FIG. 4 (*a*) PEDESTALS VIBRATING IN PHASE WITH ROTOR AND SUPPORTING ELASTIC STRUCTURE; (*b*) PEDESTALS MOVING IN OPPOSITE PHASE

introduction of any disturbance would be a measure of the flexural effect.

The sensitivity to either mode of vibration might be tested by making a trial run with the weight first, at *A*, Fig. 4(*b*), then leaving *A* in, with a similar weight at *B*. From these runs, the unit vectors for the weights at *A* and *B* are obtained. Finally, a test run is made with *B* rotated 180 deg to *B'*, forming a couple with *A*. A comparison of the resulting vectors with the vectors to be expected by using the data from the first two runs should indicate directly any difference in sensitivity to the two modes of vibration.

It is understood of course that, in the foregoing discussion, a definite operating speed is assumed, and both the lateral and vertical components will undergo independent changes at other speeds. Rushing and Rose[8] have reported an extreme case where vibrations both at the operating speed and a lower critical speed were corrected only after taking into account the flexural effect with axial locations.

The Fundamentals of Three-Dimensional Photoelasticity[1]

M. M. FROCHT.[2] The fundamental questions in connection with the possible extension of the photoelastic method into the domain of three-dimensional problems are: First, Is the stress pattern which is obtained by slicing a model, which is stressed at a high temperature and annealed to room temperature, affected by the cutting process itself? and second, Does the interpretation of this stress pattern follow the same stress-optic law which governs two-dimensional photoelasticity?

Considerable work has been done in the photoelastic laboratory of the Carnegie Institute of Technology to determine the answers to these questions and it is a source of satisfaction to report that our findings completely corroborate the results obtained by Oppel, Hiltscher, and Kuske in Germany and by Hetényi in this country regarding the elastic behavior of bakelite at high temperatures, as well as the magnitude of the fringe value given by the author in the paper under discussion.

Our experiments, like those of the author, show that a frozen stress system is not affected by being cut in any manner whatsoever. Fig. 1 shows a frozen stress pattern of a bar with a circular hole in a field of pure tension, while Fig. 2 shows the stress pattern after two circular holes and a groove have been cut in the same model. Our work further shows that in a stress range of from 20 to 200 psi the behavior of bakelite at temperatures equal to or exceeding 110 C is completely elastic, that the optical sensitivity at 112 C is 26.3 times as great as at room temperature, and that it remains essentially constant above 110 C. Fig. 3 shows the variations in the fringe value in a series of twelve tests. It is seen that none of the results exceed the average by more than plus or minus 2 per cent. These results have been obtained from constant-load tests with tension models. No such consistency in the results is obtainable from constant-deformation tests, especially at low stresses.

Dr. Hetényi has made a significant contribution by bringing

FIG. 1 FROZEN OR FIXED STRESS PATTERN OF A BAR WITH A CIRCULAR HOLE IN TENSION
(Load, 5.04 lb; width 0.847 in.; thickness, 0.258 in.; fringe value, 12.22 psi tension.)

FIG. 2 SAME BAR AS IN FIG. 1 AFTER TWO HOLES AND A GROOVE HAVE BEEN CUT
(No disturbance of the stress pattern due to cutting.)

[2] Associate Professor of Mechanics, Carnegie Institute of Technology, Pittsburgh, Pa. Mem. A.S.M.E.

into the field of photoelasticity the current theory of molecular structure of phenolic resins which throws much light on the puzzling phenomenon of frozen loadless stress patterns. One may perhaps question his conclusion that ". . . . . the observed birefringence is also due *entirely*[3] to the deformations of this element in the resin." If this statement is to be interpreted as meaning that only the permanently elastic network of the bakelite is responsible for the final optical effects a question would arise as to why the bulk of the material, which ultimately returns to its normal optical properties, makes no contribution to this birefringence? Does the theory assume that this material is strainless? If so, wouldn't that mean that a body maintains an elastic material in a state of strain without itself being strained? It would seem to the writer more reasonable to assume that the final stress pattern is the result of the combined effect of all the molecules in the model, and not only of the permanently elastic network.

[3] Italics by the writer.

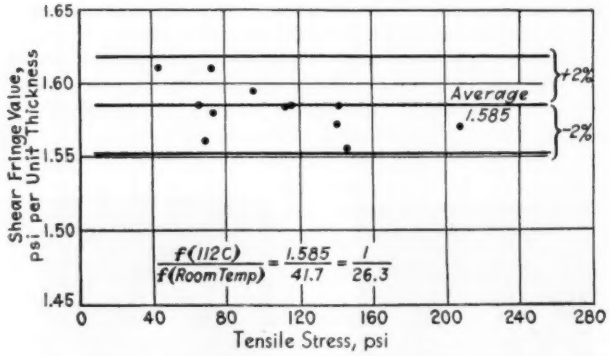

FIG. 3 SHEAR FRINGE VALUE OF BAKELITE-BT-69-893 AT 112 C WHEN STRESSES ARE FROZEN

Fig. 4 shows an attempt to use the relatively large strains produced at high temperatures as an aid in the determination of the sum of the principal stresses in two-dimensional problems. With small loads, variations of several thousandths of an inch can be obtained in models 1/4 in. thick and measured with a fair degree of accuracy with ordinary micrometers or dial gages. The curves shown in Fig. 4 represent the changes in the thickness of the model the stress pattern of which is shown in Fig. 2, in which the uniform stress was 23 psi. This method of procedure may prove of some value for first approximations in determining factors of stress concentration. It is extremely simple and necessitates no equipment other than an oven, micrometer, or dial gage, and model.

To return to three-dimensional problems the writer would like to make one suggestion which may simplify the equipment and procedure in the determination of the direction of the principal stresses as well as the difference of one pair at any point of a general section cut from a body in an arbitrary direction. If such a plate be placed in a transparent container filled with carbon disulphite and this container placed in the field of an ordinary photoelastic polariscope, then by gradually turning the submerged

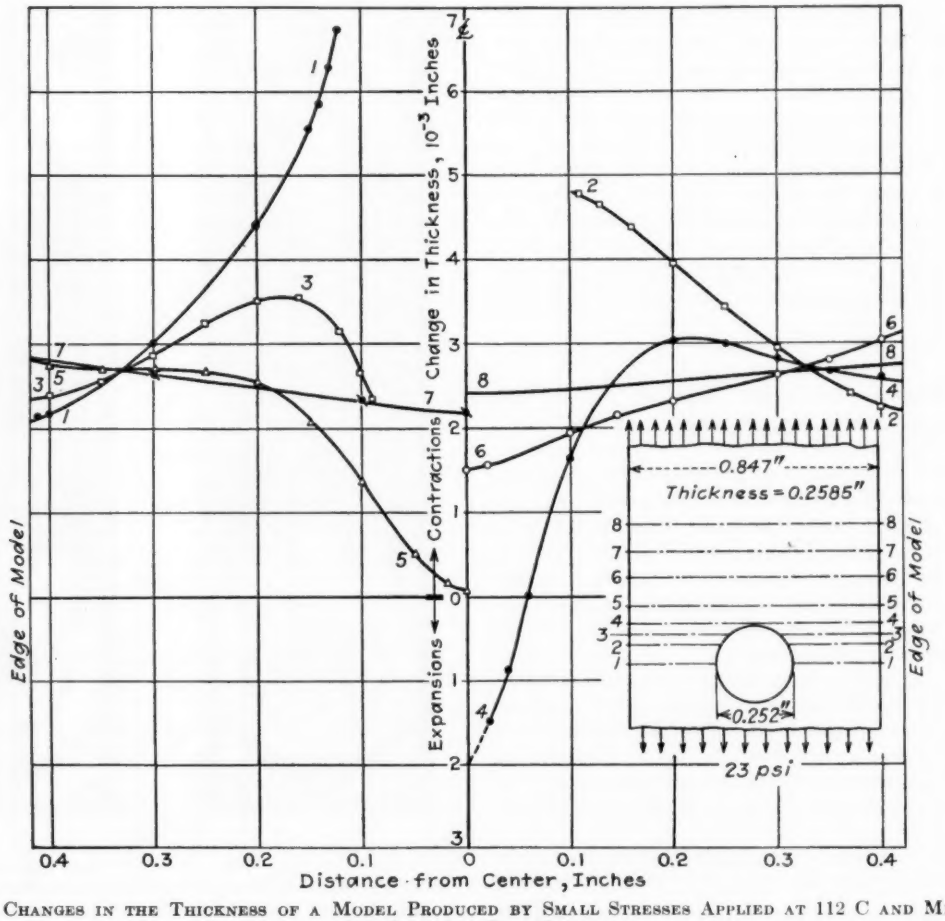

FIG. 4 CHANGES IN THE THICKNESS OF A MODEL PRODUCED BY SMALL STRESSES APPLIED AT 112 C AND MEASURED BY ORDINARY DIAL GAGES

section of the model about horizontal and vertical axes it should seem possible to determine the directions of the principal axes at every point as well as the difference of one pair of principal stresses. These directions should coincide with the positions which would give the clearest photoelastic image at the points in question.

Dr. Hetényi is to be congratulated for having made an important contribution in the extension of the science of photoelasticity to space problems.

RAYMOND D. MINDLIN[4] AND DANIEL C. DRUCKER.[5] Dr. Hetényi's discovery and explanation of the extraordinary properties of certain resins at elevated temperatures places the freezing procedure, recently developed for three-dimensional photoelasticity, on a sound physical basis. The optical properties of slices cut from the frozen model may now be accepted with confidence as indicating very closely an elastic state of stress.

When analyzing the fringes observed in a slice cut from a three-dimensional model, care must be taken to distinguish between their significance and the significance of the fringes obtained in the ordinary two-dimensionally stressed plate. In the latter case, the fringes are loci of points of constant principal-stress difference but, for the former case, this is usually not true. In this connection the author's remarks in footnote 20 are somewhat misleading.

Dr. Hetényi states that, in a bar subjected to torsion, the principal stresses are located in a plane making an angle of 45 deg with the axis of the bar. If this were true, the fringes observed in the 45-degree slice could be interpreted according to the usual two-dimensional methods. However, a more detailed examination of the stress distribution shows that at most points of the section none of the three principal stresses lies in this plane. Furthermore, the orientations of the principal stress directions with respect to the plane of the slice vary from point to point. Except for very special cases, slices cut from a three-dimensionally stressed model will have this characteristic. In order to correctly translate the fringe pattern into terms of stress, it is generally necessary to make measurements and calculations in addition to those made in two-dimensional work. Most important of these is the determination of the orientations of the optic axis in the artificial crystals produced by the stress.

For torsion, it can be shown that one of the optic axes at each point in the bar is parallel to the axis of the bar and the second optic axis is perpendicular to the first. The orientation of the first optic axis is thus known a priori while the orientation of the second may be calculated from data obtained by observations on the slice analogous to the isoclinic determinations of two-dimensional photoelasticity. With these two orientations known, the information obtained from the fringe pattern may be converted to values of principal stresses.

The section at 45 deg to the axis of the bar is not the only one on which observations can be made to yield the distribution of shearing stress over the cross section. It does show the greatest number of fringes, but any other section, even a normal one, gives sufficient data when viewed properly. However, for no section are the fringes contours of constant principal shear.

Knowing the stress distribution, one can predict the fringe pattern. For example, it can be shown that light at normal incidence to any section of a circular bar (under torsion) will produce circular fringes and that at oblique incidence the pattern becomes elliptical.

AUTHOR'S CLOSURE

It is gratifying to know that by using sufficiently high annealing temperature Professor Frocht obtained results coinciding with those of the writer. This fact itself, since the annealing time in the two cases was presumably different, seems to prove also that at elevated temperature the material is truly elastic and shows no creep which is so easily observable in room temperature tests.

The statement that ". . . . . the observed birefringence is also due *entirely* to the deformation of this element in the resin" was made for the high-temperature state and the author maintains the belief that for that state the statement holds accurately true. Doubt could exist only for the case when, after the annealing process, the load is removed from the specimen. Then, the reaction forces will be transmitted to the solidified fusible part whose stress or strain will then participate in the birefringence of the sample. But even this participation will be small, which is proved by the fact that by unloading the piece the number of fringes decreases only in the ratio of 25 to 26.

The author wishes to correct his statement made in the paper regarding the chemical composition of bakelite BT-61-893. This material is not phenolic resin, but is glycerine phthalic anhydride. Its molecular structure has however the same characteristics as the ones described in the paper for phenol formaldehyde resins and therefore the explanation given in the paper regarding the freezing process remains essentially the same.

The proposal to determine the sum of principal stresses from lateral measurements on the frozen sample is of practical value. The method has been used also by the author in determining stresses in rotating disks by the freezing procedure.[6]

The author appreciates the remarks of Messrs. Mindlin and Drucker regarding the corrections to be made when determining the shearing-stress distribution in the cross section of a bar subjected to torsion. When writing the paper he was already aware of the fact that such corrections are necessary but did not go into details since for several other reasons the method does not seem suitable for determining shearing-stress distribution in the cross section of a twisted bar. In such cases the main point of interest would be to obtain stress-concentration factors for reentrant corners of the cross section, but at those places, because of the oblique section and the finite thickness of the slices, the definition of the fringes is poor; therefore, the method cannot compete with the membrane-analogy test which seems to be eminently suitable for problems of this type. On the other hand, by the author's method one can solve problems of torsional stress distribution where the membrane analogy is unusable. Such a case was presented by him in Figs. 13 to 15 where also no correction of the nature indicated by Messrs. Mindlin and Drucker is necessary.

Friction Coefficients for the Compressible Flow of Steam[1]

J. I. YELLOTT.[2] The growing importance of superposition in power-plant practice has given rise to difficult problems in the low-pressure lines leading from the reducing valves. It is encouraging to learn that the familiar friction factors can be used with confidence.

During the last year, experiments similar to those reported by the author have been carried out at Stevens Institute of

[4,5] Department of Civil Engineering, Columbia University, New York, N. Y.

[6] "The Application of Hardening Resins in Three-Dimensional Photoelastic Studies," by M. Hetényi, *Journal of Applied Physics*, vol. 10, no. 5, May, 1939.

[1] Paper by Joseph H. Keenan, published in the March, 1939, issue of the JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 61, p. A-11.

[2] Assistant Professor of Mechanical Engineering, Stevens Institute of Technology, Hoboken, N. J. Jun. A.S.M.E.

Technology, using a 36-ft length of standard 1-in. pipe. The principal difference between this apparatus and the author's lies in the use of a reducing valve directly ahead of the test section instead of a flow nozzle. The character of the flow patterns must be decidedly different in the two cases, but preliminary test results show surprisingly good agreement with those presented in the paper.

The author's assumption that no moisture forms in the pipe when the steam is initially superheated is probably correct. Experiments carried out by the writer on a nozzle with a very long throat indicate that supersaturation prevails under such conditions.

It should be noted that the friction coefficients presented in the paper are just one quarter of the usually quoted friction factors.[3] This discrepancy doubtless arises from the definition of the wall-friction force in terms of the friction coefficient.[4]

Students of this subject will be glad to know that a complete translation[5] of Frössel's paper is available.

Author's Closure

Professor Yellott's corroboration of the assumption that the liquid phase does not form in the pipe is most welcome.

Some doubts linger as to whether any one definition of a friction factor is "usually quoted" in the literature of fluid mechanics. However, no confusion need arise in this instance because the definition employed is clearly stated in the second paragraph of the Appendix.

The Calculation of Steam-Turbine Reheat Factors[1]

J. R. Finniecome.[2] Although much attention has been given in the past to the accurate determination of the reheat factor, still further new methods, formulas, or data on this subject are welcome. This problem is of vital importance to turbine designers.

In comparing the author's published formulas with those already in existence and used, it is found that his formula for the reheat factor for superheated steam, according to Equation [6], agrees with an already well-established one. No further comments are thus required. One has only to study H. M. Martin's classic publication, referred to in the author's Bibliography (9). At the time, this attracted general attention for it contained the first exhaustive mathematical analysis on reheat factors.

1 *Superheated Steam.* Although Martin's formulas and tables were published exactly twenty years ago, they are still in general use. His formula for the superheated region is accepted by other authorities. One is thus not surprised to find that the author, after applying the basic principles of thermodynamics, arrives ultimately at the same formula for the reheat factor for an infinite number of stages.

It is rather fortunate that the author has compared the graphical method of determining the reheat factor with the values obtained by Equation [6] and proved that these agree very closely as shown in his Table 1, the discrepancy being minute.

The graphical method has been applied successfully for many years and is to some extent used today. However, during the last decade the improvement in the stage efficiency, the increase in the number of stages, the higher pressures and temperatures have made it essential for the designer to determine the reheat

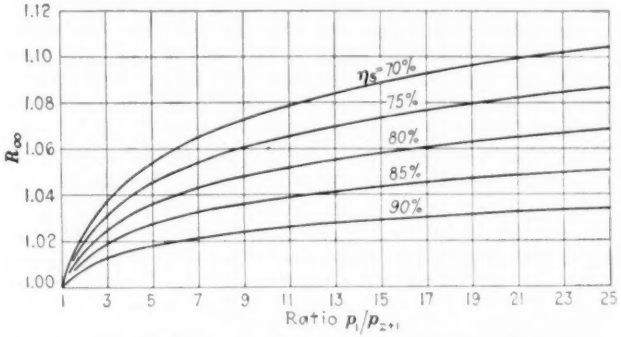

Fig. 1 Reheat Factors for Superheated Steam: Plotted as Function of Pressure Ratio
(Infinite number of stages.)

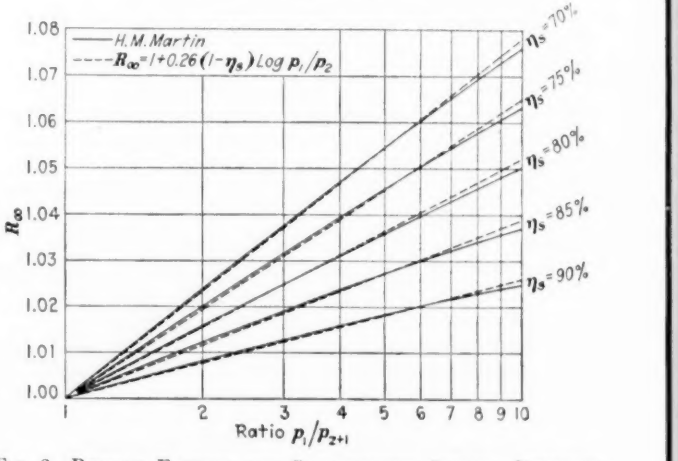

Fig. 2 Reheat Factors for Superheated Steam: Pressure Ratio Plotted on Logarithmic Scale
(Infinite number of stages; values of p_1/p_{z+1} up to 10.)

factor more accurately by calculating the values from a formula. An increase in stage efficiency gives a decrease in the value of the reheat factor, so that accuracy is of considerable importance.

The writer has plotted in Fig. 1 the reheat factors for an infinite number of stages for the superheated region as a function of the pressure ratio at the various stage efficiencies generally used in turbine practice today. Fig. 2 shows the same relationship with the pressure ratio plotted on a logarithmic scale for

the values of p_1/p_{s+1} up to 10 and in Fig. 3 for values up to 50. These reheat factors were calculated from Martin's formula, which is equivalent to Equation [6] of the author's paper.

The writer has derived from these curves a simple formula which is represented by dotted straight lines through the origin; these lines approach as closely as possible to the accurate curve. It will be found that the complicated exponential formula by Martin can be simplified and thus we get

(*a*) For a pressure ratio 1 to 10

$$1 + \rho_\infty = 1 + 0.26(1 - \eta) \log_{10} (p_1/p_{s+1}) \quad \ldots\ldots [1]$$

(*b*) For a pressure ratio 1 to 50

$$1 + \rho_\infty = 1 + 0.248(1 - \eta) \log_{10} (p_1/p_{s+1}) \quad \ldots\ldots [2]$$

Usually the pressure ratio does not exceed 10, so that Equation [1] can be applied over the complete range. A closer examination of the full-line curves and the dotted lines of Figs. 2 and 3 indicates that the difference in the values for the reheat factors is very minute.

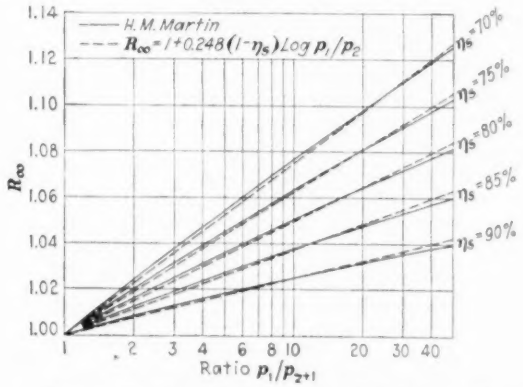

FIG. 3 REHEAT FACTORS FOR SUPERHEATED STEAM; PRESSURE RATIO PLOTTED ON LOGARITHMIC SCALE
(Infinite number of stages; values of p_1/p_{s+1} up to 50.)

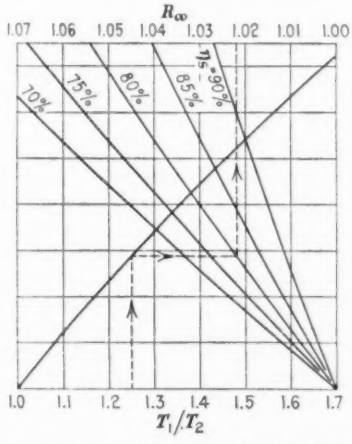

FIG. 4 REHEAT FACTORS OF SATURATED STEAM; PLOTTED AS RATIO OF INITIAL TO FINAL ABSOLUTE TEMPERATURE
(Author's Equation [10].)

2 *Saturated Steam.* For the saturated-steam region the author has derived, on applying the principles of thermodynamics, a very interesting relationship of the initial and final absolute temperatures to the reheat factor. This is represented by his Equation [10]. It will be found that the mathematical solution to this expression is too complicated for practical use, so the writer decided to solve this equation graphically. This is shown in Fig. 4, the basis of plotting being the ratio of the initial to the final absolute temperature. The author's Equation [10] can be modified as follows:

$$\frac{\rho_\infty}{(1-\eta)}\left(1 + \frac{\eta}{1-\eta} \times \frac{\rho_\infty}{2}\right) = \frac{T_1}{T_1 - T_{s+1}} \log_e \left[\frac{T_1}{T_{s+1}} - 1\right] \quad \ldots\ldots [3]$$

and by substituting $T_1/T_{s+1} = k_T$ we get

$$\frac{\rho_\infty}{1-\eta}\left(1 + \frac{\eta}{1-\eta} \times \frac{\rho_\infty}{2}\right) = \left[\frac{1}{1-k} \log_e k - 1\right] \quad \ldots [4]$$

So far as the writer is aware this is the first time the reheat factor for saturated steam has been plotted as a function of the ratio of the absolute temperatures. By following the arrows in Fig. 4, one is able to read off the reheat factor for a specified absolute-temperature ratio, based on the saturated temperature of the initial and final pressures.

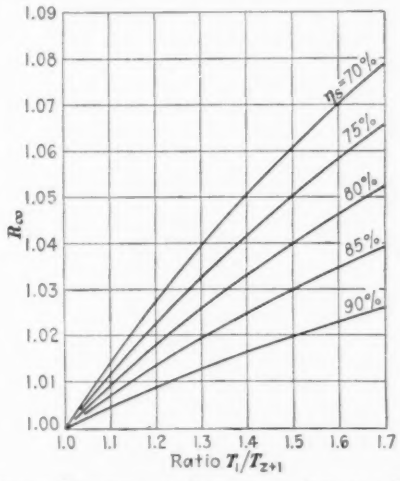

FIG. 5 REHEAT FACTORS OF SATURATED STEAM; PLOTTED AS FUNCTION OF ABSOLUTE TEMPERATURE
(Author's Equation [10].)

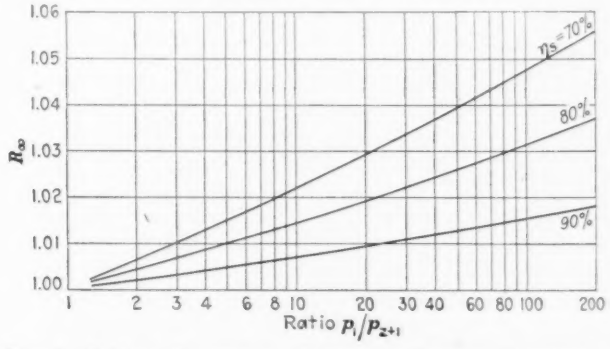

FIG. 6 REHEAT FACTORS OF SATURATED STEAM; PLOTTED AS FUNCTION OF PRESSURE RATIO
(Due to H. M. Martin.)

In Fig. 5 the reheat factor is simply plotted directly as a function of the absolute temperature without applying any intermediate curve. The values can thus be read off directly. The writer has checked the reheat factors obtained from the curves plotted in Fig. 5, derived from Equation [10] with those obtained by Martin, plotted in Fig. 6, as a function of the pressure ratio and he finds they agree.

In 1935, H. G. Yates expressed the reheat factor for the saturated region also as a function of the initial and final absolute temperatures. In substituting into his original formula the

symbols used in this paper we get for an infinite number of stages

$$1 + \rho_\infty = 1 + (1 - \eta)\frac{T_1 - T_{z+1}}{2T_{z+1}} \quad \ldots\ldots\ldots [5]$$

This equation can be written in this simple form

$$1 + \rho_\infty = 1 + (1 - \eta)\frac{1}{2}\left(\frac{T_1}{T_{z+1}} - 1\right) \quad \ldots\ldots\ldots [6]$$

This formula is graphically represented on the basis of the ratio of the absolute temperatures as shown in Fig. 7. It is found that the values derived from Yates's formula are much higher

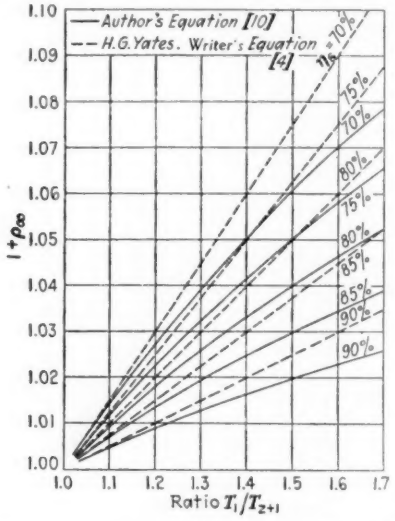

FIG. 7 REHEAT FACTORS OF SATURATED STEAM; PLOTTED ON BASIS OF RATIO OF ABSOLUTE TEMPERATURE (Author's Equation [10]; writer's Equation [7].)

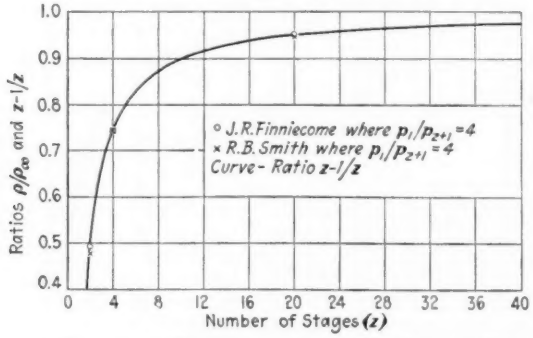

FIG. 8 EFFECT OF NUMBER OF STAGES ON REHEAT FACTOR

than the author's calculated from his Equation [10]. This comparison is shown in Fig. 7, where the dotted lines are Yates's values and the full-line curves are based on the author's Equation [10], which is more accurate.

3 *Effect of the Number of Stages on the Reheat Factor.* The foregoing discussion and curves have referred to the reheat factor for an infinite number of stages. The author gives a painstaking derivation of the correction factor to be applied to the reheat factor for an infinite number of stages, so as to obtain those at a specified number of stages. The now generally accepted formula is $(z - 1)/z$, which is very accurate indeed and the reheat gain is then calculated from

$$\rho = \frac{z - 1}{z}\rho_\infty$$

This has been used by the author in comparing the more accurate values determined analytically and expressed by Equation [5*a*] of this paper.

It may be worth while to mention here that A. Zinzen gives for this correction factor the following slightly simpler equation

$$\frac{1 + \rho}{1 + \rho_\infty} = \eta\left[\frac{1 - (p_1/p_{z+1})^{\frac{n-1}{n}\frac{1}{z}}}{1 - (p_1/p_{z+1})^{\frac{\eta}{z}\frac{n-1}{n}}}\right] \quad \ldots\ldots\ldots [7]$$

In Table 1 are given the values calculated by Equation [7] for the cases considered by the author. Fig. 8 shows these plotted on the basis of the number of stages.

E. L. ROBINSON.[3] This paper attempts to present in algebraic form a complicated property of steam. Although the algebra looks formidable when set in type the actual expressions, Equation [6] presented in Fig. 4 and Equation [10] presented in Fig. 6, are really comparatively simple expressions. At best, the expressions of formal algebra can only represent complicated physical properties to a certain degree of approximation. Under such circumstances, it has always been the preference of the writer for tabular or graphic presentation of the properties rather than approximate representation by formulas. However, it must be admitted that a formula is very convenient for computation and for assuring consistency of tabular values.

In following through the rather large number of closely approximate assumptions made by the author, it becomes increasingly difficulty to visualize what the outcome might be in final accuracy.

In this respect comparison with Professor Thatcher's results[4] is very valuable. Thus, if the author's Fig. 4 and Professor Thatcher's Fig. 7 are plotted on the same semilog sheet, the degree of agreement between the perfect gas formula and the step-by-step calculation becomes evident and the magnitude of the deviations is easily seen. It must, of course, be recognized that the adiabatic index for steam is subject to variation. The writer has carried out a number of sample calculations extending from the superheated region into the wet region and finds the results for the most part agree within a minor fraction of 1 per cent.

In the derivation of Equation [10] for the wet region, the assumption that temperature variation is proportional to enthalpy change is approximately the same as that made by the writer on the suggestion of Prof. J. H. Keenan in preparing the report,[5] referred to by the author. In the report the use of that assumption was confined to the superheated region entirely. The deviations from accuracy in the wet region were investigated and the corrections published in the report. The use of this assumption for expansions exceeding 100 Btu led to errors exceeding 0.1 Btu and, consequently, this assumption was rejected for greater expansions.

Direct integration of Equation [9] gives the following expression for reheat factors which appears to the writer quite as convenient for computation as the quadratic form given in Equation [10]

$$1 + \rho = \frac{e^{\eta B} - (1 - \eta)}{\eta e^{\eta B}}$$

---

[4] "Reheat Factors for Expansions of Superheated and Wet Steam," by C. G. Thatcher, published in the December, 1938, issue of the JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 60 1938, p. A-161.

[5] "Reheat Factors," by E. L. Robinson, *Mechanical Engineering*, vol. 50, February, 1928, pp. 155–156.

In this expression B is the function of the temperature ratio, which appears on the right-hand side of Equation [10], namely,

$$B = \left[\frac{T_1}{T_1 - T_{z+1}}\left(\log_e \frac{T_1}{T_{z+1}}\right) - 1\right] = \left(\frac{\theta \log_e \theta}{\theta - 1} - 1\right)$$

where $\theta = T_1/T_{z+1}$.

This alternative expression appears to agree closely with the values presented in the author's Fig. 6 and, of course, involves the same assumption as regards variation of enthalpy and temperature. It is to be noted that this expression gives the reheat factor in terms of the stage efficiency and the temperature ratio. For a definite efficiency of 0.80, as chosen for Fig. 6, a single curve suffices to define the result more simply than the family in Fig. 6. Thus, for the wet region:

Temperature ratio	= 1.05	1.10	1.15	1.20	1.25	1.30	1.35	1.40
Reheat gain, $\eta = 0.80$	= 0.0049,	0.0095,	0.0139,	0.0181,	0.0221,	0.0260,	0.0296,	0.0331

The author gives a more exact expression for the saturated region in Equation [12], of which the right-hand parenthesis may be used for the value of B in Equation [10]. A chart or table of "wet" reheat factors showing how Equation [12] differs from Equation [10] would be welcome.

C. G. THATCHER.[6] The writer wishes to express his appreciation of the author's fine work in approaching this subject from an analytical angle, and also for the excellent spirit of cooperation which he has exhibited at all times toward the writer and his work.

100	10.0	10		1022.5	164.5	1.0187	1.0174
100	20.0	5		1067.5	119.5	1.0136	1.0126

It will be noted from Tables 1 and 2 of comparative values that in the superheat region the values check very closely. Some discrepancy may creep in through the author's assumption of a constant value of k in the equation PV^k = constant. This does vary some through the superheat region, as shown by Keenan and Keyes.[7] In the wet region there is a close agreement in the figures, although at higher initial pressures the author's values are somewhat higher than those of the writer.

In the author's Equation [12], he introduces the specific heat of the liquid with the assumption that it remains constant. This may possibly be the cause of the discrepancy, since at higher initial pressures the value of specific heat does increase beyond unity.

AUTHOR'S CLOSURE

Since publication of the paper, it has been possible to reduce the mathematical relations which define the reheat factors in the superheat and the saturated regions to rapidly converging series suitable for slide-rule work. Equation [6] for the superheated reheat region may be written

$$1 + \rho_\infty = 1 + \frac{1-\eta}{2}\,\frac{k-1}{k}\log_e \frac{P_1}{P_{z+1}} - \left(\frac{k-1}{k}\right)^2 \frac{1}{12\eta}\{9 - \eta^5 - (\eta - 1)^2(\eta + 2)^3 - (1 + 2\eta - 2\eta^2)(\eta + 1)^3\}\left[\log_e \frac{P_1}{P_{z+1}}\right]^2 \quad \ldots\ldots\ldots [8]$$

The first three terms of Equation [8] yield results which are accurate to within 0.1 per cent for pressure ratios as high as 50. For the most common values, namely, $\frac{k-1}{k} = 0.225$ and $\eta = 0.80$, this expression becomes

$$1 + \rho_\infty = 1 + 0.225 \log_e \frac{P_1}{P_{z+1}} - 0.000492\left[\log_e \frac{P_1}{P_{z+1}}\right]^2 \quad \ldots [9]$$

For Equation [10] of the paper, representing approximately the saturated reheat factor, there can be written

$$\rho_\infty\left(1 + \frac{\eta}{1-\eta}\,\frac{\rho_\infty}{2}\right) = \frac{1-\eta}{2}\,\frac{T_1 - T_{z+1}}{T_{z+1}}\left\{1 - \frac{1}{3}\left(\frac{T_1 - T_{z+1}}{T_{z+1}}\right) + \frac{1}{6}\left(\frac{T_1 - T_{z+1}}{T_{z+1}}\right)^2 - \frac{1}{10}\left(\frac{T_1 - T_{z+1}}{T_{z+1}}\right)^3 + \frac{1}{15}\left(\frac{T_1 - T_{z+1}}{T_{z+1}}\right)^4\right\} \quad \ldots\ldots\ldots [10]$$

These relations may be of value to those working with the reheat problem.

Mr. Finniecome refers to the work of Martin in connection with the analysis of reheat factors. The author is familiar with Martin's classic study and it has not been his intention to claim any originality for the superheated reheat factor expressed by Equation [6] of the paper. However, this result is merely a simplification of the more complete relation expressed by Equation [5]. It is certainly in the derivation of this equation that the work of Martin and the author differs.

Martin's work, particularly in the superheated region, has been generally dismissed in this country as being too theoretical to give accurate results with such an imperfect vapor as steam. Consequently, there has been an overemphasis on the calculation of reheat by laborious summations on the steam charts. It is rather fortunate, in this connection, that the comparison of Table 1, of the paper, as well as the later more extended work of Professor Thatcher indicates such good agreement between analytical and practical computations.

In the saturated region, Martin's analysis leaves much to be desired. If one compares Mr. Finniecome's Fig. 6 with Fig. 6 of the paper, it is apparent that there are differences as great as 0.5 per cent. The work of Yates, which is graphical in source, leads to an expression which is a first-term approximation to the series expressed by Equation [10] of this closure. Only for small pressure ratios is it accurate.

The derivation of Zinzen, pertaining to the influence of the

number of stages on the reheat factor, and to which Mr. Finniecome refers, is based upon the assumption that the pressure ratio is uniform over each stage. Actually, this assumption is not even close to the truth on a turbine of normal design, although it must be admitted that it yields results, as Mr. Finniecome points out, which are in good agreement with the more exact expression represented by Equation [5] of the paper.

Mr. Robinson's remarks are always of interest, particularly so in this instance, in view of his past experience with the problem of reheat. He has succeeded in integrating directly the left side of Equation [9] of the paper, whereas the author was able to achieve this result only approximately.

The differences are small between the saturated reheat factor calculated by Equation [12] and by Equation [10], both of the paper. Actually the complicated relation represented by Equation [12] can be expressed as follows:

$$\rho_\infty \left(1 + \frac{\eta}{1-\eta}\,\frac{\rho_\infty}{2}\right) = (1-\eta)\left\{\frac{T_1 \log_e \dfrac{T_1}{T_{z+1}}}{T_1 - T_{z+1}} \times f(T) - 1\right\} \qquad \ldots\ldots [11]$$

where, for $c = 1.0$

$$f(T) = 1 - \frac{\dfrac{1}{12}\left(\dfrac{T_1 - T_{z+1}}{T_{z+1}}\right)^2\left\{1 - 1.5\left(\dfrac{T_1 - T_{z+1}}{T_{z+1}}\right) + 1.78\left(\dfrac{T_1 - T_{z+1}}{T_{z+1}}\right)^2 - 1.96\left(\dfrac{T_1 - T_{z+1}}{T_{z+1}}\right)^3\right\}}{S - \log_e \dfrac{T_1}{492} + \dfrac{1}{2}\left(\dfrac{T_1 - T_{z+1}}{T_{z+1}}\right)\left\{1 - \dfrac{2}{3}\left(\dfrac{T_1 - T_{z+1}}{T_{z+1}}\right)\right\}} \qquad \ldots\ldots [12]$$

These series when used in conjunction with Equation [10] of this closure are quite easily handled. In Table 3, herewith, are typical comparative values of saturated reheat factors computed from the analytical expression and also graphically by Professor Thatcher. The differences are small.

[a] Reference is to equation in original paper.

Professor Thatcher's graphical analysis of the reheat problem is timely and his comparative tabulation between the analytical and graphical results substantiates the work that has been done. In regard to the saturated analysis—while it is true that the specific heat of the liquid is far from constant, it is also true that over the range of practical turbine design the variation when applied in Equation [12] of the paper is insignificant. This is further borne out by the comparison in Table 3 of this closure. Actually, the differences that do exist between the two methods of solution can be partly explained by the fact that Professor Thatcher presents his reheat factors as a function of the isentropic-enthalpy drop. It is easy to demonstrate that entropy is also a necessary variable.

Reheat Factors for Expansions of Superheated and Wet Steam[1]

E. M. Fernald.[2] The use of PV^k = constant for the isentropic, with a value of k pertaining to the region in which the process takes place, will yield values of the available energy (isentropic change of enthalpy) precise to 0.01 Btu without any difficulty, although the Keenan and Keyes tables[3] are precise only to 0.1 Btu. Calculation of available energy to 0.01 Btu as the difference of two enthalpies, each run out to 0.01 Btu in the course of interpolation, as the author does, seems less desirable.

The mention of perfect-gas laws by R. B. Smith,[4] in connection with the PV^k equation for isentropics, brings up a point in thermodynamics which appears to be widely misunderstood. It is true that a perfect gas, characterized by constancy of PV/T, does conform to that relation, k being then the ratio of specific heats C_p/C_v. It is not true, however, that conformity to a relation of the general form PV^k = constant for individual isentropics necessitates perfect-gas behavior to the extent that PV/T is constant over all states. The assumption is not needed. It is only necessary to make use of the convenient fact that isentropic expansion of superheated steam, wet steam, and other fluids, proceeds according to the relation PV^k = constant, at least near enough for engineering. The k is merely a constant, approximately, and has no direct relation to the ratio of specific heats. Indeed, for fluids approaching incompressibility, k approaches infinity (volume constant), whereas the ratio of specific heats does no such thing.

Proceeding on this basis, we get for the difference between internal energies, calculated as the work for expansion in a cylinder,

$$U_1 - U_2 = \int_2^1 Pd\,V/J = \frac{P_1V_1 - P_2V_2}{J(k-1)}, \text{ Btu}$$

For the difference between enthalpies, or the available energy, we get, from $H = U + PV/J$,

$$H_1 - H_2 = (U_1 + P_1V_1/J) - (U_2 + P_2V_2/J)$$

$$= \frac{P_1V_1}{J(k-1)} + \frac{P_1V_1}{J} - \frac{P_2V_2}{J(k-1)} - \frac{P_2V_2}{J}$$

$$= \frac{k}{J(k-1)}\,(P_1V_1 - P_2V_2), \text{ Btu}$$

[1] By C. G. Thatcher. Published in the December, 1938, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 60, 1938, p. A-161.

[2] Professor, Department of Mechanical Engineering, Lafayette College, Easton, Pa. Mem. A.S.M.E.

[3] "Thermodynamic Properties of Steam," by J. H. Keenan and F. G. Keyes, John Wiley & Sons, Inc., New York, 1936.

[4] This is a combined discussion of the present paper and the paper, "The Calculation of Steam-Turbine Reheat Factors," by R. B. Smith, published in the December, 1938, issue of the Journal of Applied Mechanics, Trans. A.S.M.E., vol. 60, 1938, p. A-156.

This agrees with R. B. Smith's relations for superheated steam. Perfect gases thus need not be mentioned.

To prove that PV^k = constant can be used for individual isentropics where PV/T = constant could not possibly be used over all states, only wet steam need be considered. Over the common region of wet steam, k is near enough to constant for most engineering, whereas PV/T varies, of course, widely. It is of interest, however, that PV/T is about as constant for a particular isentropic of wet steam as k is. As PV^k = constant applies reasonably well to isentropic expansion of wet steam, the writer surmises that Mr. Smith, had he chosen, could have treated wet steam acceptably for engineering by the same method that he used for superheated steam.

J. R. Finniecome.[5] There has been a considerable controversy concerning the correct method to determine most accurately the value of the reheat factor. In the step-by-step calculation the author has succeeded in his endeavor to present a set of very interesting curves on the reheat factor for both the superheated and saturated region.

The object of the writer's contribution is to satisfy the turbine designer, who is particularly interested in the reheat factor, that the full-line curve in the author's Fig. 5, representing the average of the figures obtained from his analysis, corresponds actually to those determined by the following formula generally used for the superheat region

$$RF_\infty = \frac{1}{e_s} \cdot \frac{\left[1 - (p_2/p_1)^{e_s \frac{n-1}{n}}\right]}{\left[1 - (p_2/p_1)^{\frac{n-1}{n}}\right]}$$

where e_s = the constant stage efficiency
p_1 = the initial pressure
p_2 = the final pressure
n = 1.3 (superheated steam)
$\frac{n-1}{n}$ = 0.2308

The reheat factors for an infinite number of stages and for a constant stage efficiency of 85 per cent at various pressure ratios are calculated from the above formula and are given in Table 1.

TABLE 1 REHEAT FACTORS AT VARIOUS PRESSURE RATIOS

Pressure ratio p_1/p_2	Reheat factor RF_∞
2	1.0120
4	1.0238
6	1.030
8	1.0342
10	1.0371
20	1.0473
50	1.0602

When plotting these values in the author's Fig. 5, it is found that they lie on the full-line curves, indicating that Equation [1] agrees as expected with the step-by-step calculation method. On analyzing the reheat factors in Figs. 7 and 8, the writer finds that they also agree exceptionally well with Equation [1]. For comparison the writer gives in the accompanying Figs. 1 and 2 reheat factors based on Equation [1] for pressure ratios up to 48 and 50, respectively, and stage efficiencies varying from 70 to 90 per cent, generally used in turbine design.

Incidentally it may be mentioned that the author's Fig. 4 confirms the already well-known relationship of the reheat factor with the number of stages.

In addition the variation of the reheat factor in the saturated region with the adiabatic heat drop without and with wetness

[5] Mechanical Engineer, 4 Rye Bank Road, Seymour Grove, Manchester 16, England.

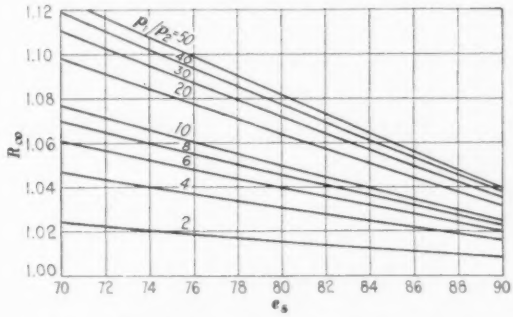

Fig. 2 Reheat Factors for Superheated Steam
(For an infinite number of stages; due to H. M. Martin.)

correction is the result of the step-by-step calculation method. These curves constitute a valuable contribution and indicate the advantage of this method of determining the reheat factors in the saturated region.

It is perhaps desirable to mention that the turbine designer would have welcomed from the author an empirical formula expressing the relationship of the reheat factor to the adiabatic heat drop and the constant stage efficiency, based on the curves of Figs. 9 and 12, respectively, to enable one to plot the reheat factor on a larger scale chart.

J. T. Rettaliata.[6] Reheat factors, based on the latest Keenan and Keyes[3] Mollier diagram, have been much needed for some time and the author has rendered a valuable service by supplying them. The existent uncertainties associated with the expansion of steam in turbines, as mentioned by the author, necessitate the use, in turbine design, of as much reliable data as can be obtained, in order to minimize the effect of these uncertainties. Hence the need for reheat factors directly applicable to the Mollier diagram in universal use in this country today.

The step-by-step method employed by the author is a tedious process but the accuracy of its results justifies its use. As stated in the paper, the enthalpy-entropy diagram is so constructed in the superheat region that, a movement in the direction of increasing entropy on the diagram, gives rise to two mutually compensating effects, tending to keep the reheat factor constant for any given pressure ratio. To justify his statement, the author determined reheat factors for a pressure ratio of 2 in various regions of the superheat field of the Mollier diagram and showed that they were essentially the same. The writer, in a mathematical treatment, wishes to present further veri-

[6] Engineer, Steam Turbine Department, Allis-Chalmers Manufacturing Company, Milwaukee, Wis.

fication of the existence of a single value of the reheat factor under the aforementioned conditions.

For an infinite number of expansions, the reheat factor may be given as the ratio of area *ABCE* to area *ABDE*, in the *P-V* diagram, Fig. 3, where *BC* represents the actual expansion, from P_1 to P_2, with exponent n; and *BD* the isentropic expansion with exponent k, where k is the ratio of the specific heats at constant pressure and constant volume.

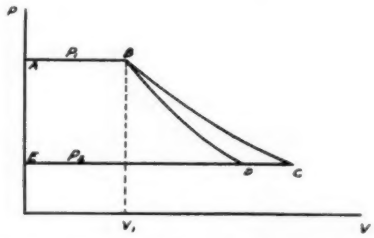

FIG. 3 ISENTROPIC AND POLYTROPIC EXPANSIONS ON A PRESSURE-VOLUME PLANE

Using the proper relations for the areas, the reheat factor may be expressed by

$$RF_\infty = \frac{\frac{n}{n-1} P_1V_1\left[1-\left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}\right]}{\frac{k}{k-1} P_1V_1\left[1-\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}\right]} \quad \ldots\ldots [1]$$

If the specific heat at constant volume is assumed to remain sensibly constant, the value of n may be shown to be

$$n = \frac{1}{1-e_s\left(1-\frac{1}{k-1}\right)} \quad \ldots\ldots [2]$$

where e_s is the stage efficiency of the expansion.[7]

If Equation [2] is substituted in Equation [1] the latter becomes

$$RF_\infty = \frac{1}{e_s}\left[\frac{1-\left(\frac{P_2}{P_1}\right)^{e_s\left(\frac{k-1}{k}\right)}}{1-\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}}\right] \quad \ldots\ldots [3]$$

Using Equation [3], reheat factors were calculated for a stage efficiency of 0.75 and pressure ratios from 5 to 50, assuming an average value of 1.3 for the isentropic exponent in the superheated region on the Mollier diagram. A comparison of the calculated results and those obtained from the $e_s = 0.75$ curve of Fig. 7 in the paper is given in Table 2.

50	1.102	1.1015	0.0454

As can be seen from the last column of Table 2, the agreement between the calculated values and those given by the author is extremely good.

In reality the isentropic exponents for superheated steam do not remain constant but have values as given by Keenan and Keyes.[8] Using the writer's Equation [3] with a stage efficiency of 0.75 and random values of pressure ratio and entropy, and isentropic exponents applicable to the particular regions of the Mollier diagram, where the expansions are occurring, reheat factors as shown in Table 3 were obtained.

TABLE 3 REHEAT FACTORS FOR STAGE EFFICIENCY OF 0.75 AND RANDOM VALUES OF PRESSURE RATIO AND ENTROPY

$\frac{P_1}{P_2}$	Entropy	Isentropic exponent	Reheat factor		Difference, per cent
			Calculated	Thatcher	
5	1.7	1.2890	1.043	1.045	0.1914
5	1.8	1.274	1.046	1.045	0.0960
10	1.8	1.3050	1.064	1.064	0
10	1.9	1.2930	1.061	1.064	0.2820
10	2.0	1.2760	1.060	1.064	0.3760
20	1.8	1.2985	1.080	1.0805	0.0460
20	1.9	1.2850	1.078	1.0805	0.2310

Here, again, close agreement exists between the calculated and the author's values.

Although by no means exhaustive, this analysis indicates that the reheat factors for a given pressure ratio remain essentially constant in the superheat region regardless of the location of the expansion on the Mollier diagram.

E. L. ROBINSON.[9] This paper gives the essential information from which reheat factors can be determined for turbine expansions. The calculations appear to have been carried out carefully with a view to presenting the reheat factors for an infinite number of stages as a cardinal property of the working fluid, steam.

It would be advantageous if reheat factors for over-all expansions from the superheated to the wet region could be presented on a single diagram like the author's Fig. 14. He does not appear to consider this feasible, and it must be admitted that interpolation is not easy among crisscrossing curves, such as characterize Fig. 14.

On the other hand, there is great virtue in being able to see at a glance the difference between reheat factors for one type of expansion as compared with another. The scheme presented for getting over-all reheat factors toward the end of the paper requires a simple three-step calculation which is easily carried out, but is sufficiently long to prevent the seeing of a dozen reheat factors at once.

The two essential diagrams are Fig. 7 for the superheated region and Fig. 9 for the wet region. In many respects, it would be desirable to have Fig. 7 presented on a semilog plot like Fig. 5, since it is difficult to make accurate readings for small pressure ratios on Fig. 7.

The importance attached to moisture correction appears to the writer to be quite out of proportion, in view of the fact that other and compensating losses have been completely overlooked. To mention only the more obvious, as the expansion progresses in the low pressure stages of the turbine in a logarithmic manner, the specific volume increases rapidly. In consequence, nozzle and bucket lengths increase rapidly. End losses, rotation losses, and packing leakages are reduced to a small percentage of what they had been. These influences tend to improve the efficiency of the low pressure stages. The increasing moisture content tends to reduce the efficiency.

There is thus good reason for the use of a condition curve of uniform efficiency for the computation of reheat factors.

[7] "Steam Turbines," by W. J. Goudie, Longmans, Green and Company, London and New York, 1922, pp. 574–576.

[8] See p. 82 of footnote 3, on p. A-140 of this issue.

[9] Turbine Engineering Department, General Electric Company Schenectady, N. Y. Mem. A.S.M.E.

There has been some lack of clearness in technical writing about this matter of moisture loss. If two identical turbines are operated, one with wet steam and the other with dry steam, the one with wet steam will have its efficiency lowered approximately in proportion to the average moisture content. This is not the same as saying that each successive stage will have a lower efficiency in proportion to the moisture content.

Thus, the only basis for the use of Fig. 12 would be a design in which the actual stage efficiencies correspond with those assumed by the author in which, in spite of all the influences making for better performance in the low-pressure region, the net over-all result would be as presented.

H. G. YATES.[10] The author's step-by-step calculation of reheat factors for a large number of particular cases must have entailed much labor. The results will be of use to all engineers interested in this subject.

Referring to Equation [2] of the paper

$$e_s = [1 - (RH/AE_{ab})]/RF_n$$

this may be rewritten in the equivalent form

$$e_s = \eta_i/RF_n,$$

where η_i is the over-all internal efficiency. This simply expresses the fact that with a constant stage efficiency, the ratio of the over-all internal efficiency to the stage efficiency is equal to the reheat factor.

The paper is based on the fundamental assumption of constant stage efficiency. Presumably this was done in order to simplify the analysis, but it must not be forgotten that in practice the state of affairs is quite otherwise. For example, in the high-pressure cylinder of a turbine designed for a pressure of about 600 lb per sq in., the stage efficiency may vary from about 78 per cent near the inlet end to 86 per cent at the exhaust end. This is a considerable variation and is inherent in the design of a steam turbine, owing to the increase in specific volume of the steam, as its pressure falls in passing through the successive stages.

A better approximation is given, in the writer's opinion, by the assumption of a straight expansion line on the Mollier diagram for that part of the expansion, which lies within the superheated region, and a suitably curved line for the wet region. The accuracy of this is very good for all but the smallest turbines. Experience soon shows the degree of curvature required in the wet region. In any event the reheat in this region is comparatively small and a slight error in the choice of the correct expansion line is not of great moment.

This assumption of a straight expansion line in the superheat region formed the basis of the writer's work on reheat calculation,[11] referred to by the author. The solution given therein is extremely simple to use and only requires the division of the complete expansion line into two sections, instead of three as in the author's method. In fact the calculation is so short in any individual case that the writer has not attempted to construct a series of curves for variation in steam conditions. Incidentally the method is applicable to any number of stages; the correction factor $n - 1/n$ for the ratio of RH_n to RH_∞, referred to by the author as being empirical, was deduced from theoretical considerations in the writer's paper.

With regard to the moisture correction, the writer is not clear why the author has chosen to include this in the reheat factor. It is usually dealt with as a separate loss, just as any other parasitic loss to which turbine blading is subject. Fig. 11 of the paper is referred to as representing a "step" of an expansion line. Presumably this is distinguished from a "stage," according to the definition of the two terms at the outset of the paper. However, the wetness loss is in large part due to the actual impact of water drops, which have not acquired the full steam velocity necessary for shockless entry, upon the leading edges of the running blades. Hence the calculation of wetness loss must relate in some measure to the condition of the steam at the actual stage points, and cannot be done simply in a series of arbitrary steps.

There is undeniably a certain amount of doubt and disagreement as to the effect on blading efficiency of 1 per cent of wetness. The author is no doubt correct in assigning part of this doubt to uncertainty in the choice of reference point. In addition the loss is not amenable to calculation or to exact measurement. It would not have been surprising if the various authorities differed even more than they do.

The best reference point on theoretical grounds is probably the condition point of the steam at nozzle discharge. In impulse blading this is approximately point *c* in Fig. 11 of the paper if considered as referring to a single stage. Some manufacturers use point *e*, which is probably a survival from the early days of turbines when detail stage calculations were not employed and only an approximate expansion line appeared on the chart. Other turbine builders use as a reference point the condition of the steam at discharge from the running blading, which is usually somewhere between points *e* and *f* of Fig. 11.

Considering various aspects of the problem, the writer is inclined to agree that, for any future estimations of the effect of wetness losses, the reference point *c* of Fig. 11 should be used, provided that this diagram is referred to a single stage and not to an arbitrary step of an expansion line.

AUTHOR'S CLOSURE

Professor Fernald points out the doubtful value of the second decimal place in calculating isentropic drops and reheats to 0.01

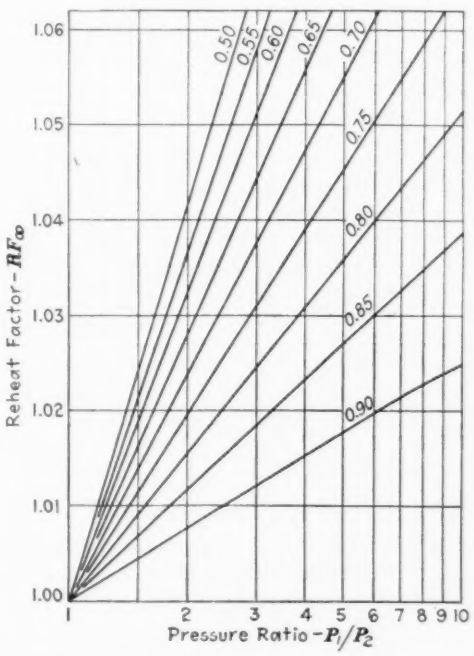

FIG. 4 REHEAT FACTORS IN SUPERHEAT REGION FOR VARIOUS STAGE EFFICIENCIES

[10] Rugby, England.

[11] "Calculations of Turbine Reheat Factor From the Geometry of the Heat Chart," by H. G. Yates, *The Engineer*, vol. 160, August 30, 1935, pp. 212–213.

fication of the existence of a single value of the reheat factor under the aforementioned conditions.

For an infinite number of expansions, the reheat factor may be given as the ratio of area *ABCE* to area *ABDE*, in the *P-V* diagram, Fig. 3, where *BC* represents the actual expansion, from P_1 to P_2, with exponent n; and *BD* the isentropic expansion with exponent k, where k is the ratio of the specific heats at constant pressure and constant volume.

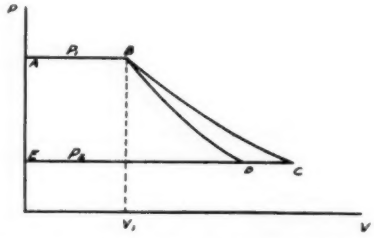

FIG. 3 ISENTROPIC AND POLYTROPIC EXPANSIONS ON A PRESSURE-VOLUME PLANE

Using the proper relations for the areas, the reheat factor may be expressed by

$$RF_\infty = \frac{\frac{n}{n-1} P_1V_1 \left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}\right]}{\frac{k}{k-1} P_1V_1 \left[1 - \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}\right]} \quad \ldots\ldots\ldots [1]$$

If the specific heat at constant volume is assumed to remain sensibly constant, the value of n may be shown to be

$$n = \frac{1}{1 - e_s\left(1 - \frac{1}{k-1}\right)} \quad \ldots\ldots\ldots [2]$$

where e_s is the stage efficiency of the expansion.[7]

If Equation [2] is substituted in Equation [1] the latter becomes

$$RF_\infty = \frac{1}{e_s}\left[\frac{1 - \left(\frac{P_2}{P_1}\right)^{e_s\left(\frac{k-1}{k}\right)}}{1 - \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}}}\right] \quad \ldots\ldots\ldots [3]$$

Using Equation [3], reheat factors were calculated for a stage efficiency of 0.75 and pressure ratios from 5 to 50, assuming an average value of 1.3 for the isentropic exponent in the superheated region on the Mollier diagram. A comparison of the calculated results and those obtained from the $e_s = 0.75$ curve of Fig. 7 in the paper is given in Table 2.

TABLE 2 COMPARISON OF REHEAT FACTORS FOR STAGE EFFICIENCY OF 0.75 AND PRESSURE RATIOS 5 TO 50

$\frac{P_1}{P_2}$	Reheat factor		Difference, per cent
	Calculated	Thatcher	
5	1.042	1.0450	0.287
10	1.064	1.0640	0
15	1.074	1.0740	0

There is undeniably a certain amount of doubt and disagreement as to the effect on blading efficiency of 1 per cent of wetness. The author is no doubt correct in assigning part of this doubt to uncertainty in the choice of reference point. In addition the loss is not amenable to calculation or to exact measurement. It would not have been surprising if the various authorities differed even more than they do.

The best reference point on theoretical grounds is probably the condition point of the steam at nozzle discharge. In impulse blading this is approximately point *c* in Fig. 11 of the paper if considered as referring to a single stage. Some manufacturers use point *e*, which is probably a survival from the early days of turbines when detail stage calculations were not employed and only an approximate expansion line appeared on the chart. Other turbine builders use as a reference point the condition of the steam at discharge from the running blading, which is usually somewhere between points *e* and *f* of Fig. 11.

Considering various aspects of the problem, the writer is inclined to agree that, for any future estimations of the effect of wetness losses, the reference point *c* of Fig. 11 should be used, provided that this diagram is referred to a single stage and not to an arbitrary step of an expansion line.

AUTHOR'S CLOSURE

Professor Fernald points out the doubtful value of the second decimal place in calculating isentropic drops and reheats to 0.01

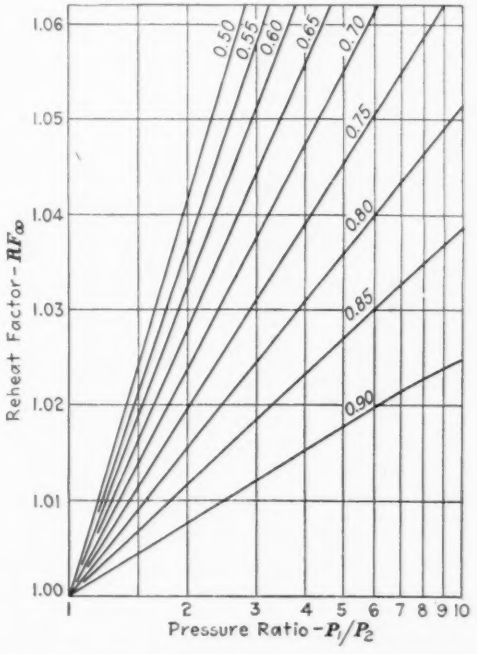

FIG. 4 REHEAT FACTORS IN SUPERHEAT REGION FOR VARIOUS STAGE EFFICIENCIES

[10] Rugby, England.

[11] "Calculations of Turbine Reheat Factor From the Geometry of the Heat Chart," by H. G. Yates, *The Engineer*, vol. 160, August 30, 1935, pp. 212–213.

Btu. He is probably correct in that our steam tables, in most cases, are not closer than 0.10 Btu. In the case of an isentropic-enthalpy drop of 100 Btu, where the constant stage efficiency is 0.80 and the reheat is 19.0 Btu, the reheat factor works out about 1.0125. If the reheat is 19.1, the reheat factor becomes 1.01125 while, if the reheat is 19.2, the reheat factor becomes 1.010. One-tenth Btu seems to make a great difference in the calculated result, especially when the isentropic drops are quite small. The use of the second decimal place is introduced in an effort to refine the work.

Mr. Finniecome suggests that an empirical formula, expressing the relationships shown in Figs. 9 and 12 of the paper, would be a welcome addition. The following expression, therefore, represents the relationship between reheat factor for an infinite number of stages, isentropic-enthalpy drop, and stage efficiency for expansion entirely within the wet region.

$$RF_\infty - 1 = 0.000525\ (I.E.D.)(1.00 - e_s)$$

This equation is based on Fig. 9. When a moisture correction is to be made, Fig. 12, add to the right-hand side of the equation

$$\frac{(I.E.D.)^{2.75}}{6 \times 10^8}$$

The equations used by Messrs. Finniecome, Rettaliata, and Ronald B. Smith to express the reheat factor for an infinite number of stages in the superheat region are really all the same equation. Apparently, they yield values which check very closely with those determined by the author in the superheat region.

As Mr. Robinson appropriately points out, it is apparently a difficult matter to present the entire range of reheat factors in a simple form such as that demonstrated in Fig. 14. The author hopes to be able to do something to simplify this problem in the near future.

In answer to Mr. Robinson's just criticism of Fig. 7 of the paper, the author herewith presents Fig. 4 which shows more accurately the values of RF_∞ in the superheat region for various constant stage efficiencies.

The stage efficiency does vary through the turbine as noted by Mr. Yates but, in a great many cases, not as much as he has indicated. If the stage efficiency at the high-pressure end is 0.78, increasing to somewhat better than 0.80, just above the saturation curve, finally falling off again in the wet region, an assumption of a constant stage efficiency of 0.80, or thereabouts, is probably justified. This eliminates the correction for moisture, for high density at the throttle end, and altogether makes the work simpler. If it is desired to approach more closely the true condition curve, the expansion may well be taken in three or four steps, using an appropriate constant stage efficiency for each of the steps.

Mathematical-Machine Determination of the Vibration of Accelerated Unbalanced Rotor[1]

By J. G. BAKER,[2] EVANSVILLE, WIS.

For an unbalanced rotor, amplitudes of vibration are given for different rates of constant angular acceleration and deceleration.[3] The setup used to obtain these results on the differential analyzer at the Massachusetts Institute of Technology is described briefly and shown diagrammatically.[4] The selection of spring constant, damping, and mass of suspended unit as a means of avoiding serious vibration in bringing a heavily unbalanced spring-mounted rotor up to speed is discussed in connection with the results.

SPRING mountings for rotors or reciprocating machinery are often designed to reduce vibration transmission to the foundation at full running speed without formal consideration of the process of getting up to speed.[5] This is permissible except in cases where the unbalance is large in comparison with other pertinent factors such as the mass of the mounted element and the acceleration with which it is brought up to speed. Where the unbalance is large the vibration of the spring-supported unit may increase rapidly enough to absorb all the energy supplied through torque to the rotor so that the machine cannot be brought to speed.

Of the number of schemes which have been used to avoid serious vibration during acceleration, perhaps the most obvious is that of adding damping. The addition of damping has the disadvantage that the vibratory force on the foundation at full speed is larger. Clamping of the spring-mounted element until the speed is well above that corresponding to the natural frequency and then unclamping has been done with good results. However, the complication of a clamping mechanism is usually objectionable.

It is the purpose of this study to consider the effects of spring stiffness, acceleration, damping, and mass of the spring-mounted element on the maximum amplitude of vibration attained during acceleration primarily to see to what extent the maximum amplitude can be reduced by the proper choice of the magnitudes of these factors.

In most actual cases of spring-mounted rotors the torque applied to the rotor by the source of power is roughly constant during most of the acceleration period, so that the angular acceleration would be also roughly constant were it not for the part of the torque which is absorbed by the vibration. Because of the building up of the vibration, a torque associated with the unbalance appears which is opposite in direction to the torque applied by the source of power and which therefore reduces the angular acceleration below that which would have taken place had there been no vibration. The equations of motion of a simple spring-mounted unbalanced rotor with a constant torque applied appear so difficult to solve or to handle in the differential analyzer in its present form that instead of constant applied torque, constant acceleration has been assumed.[6] Thus, the solution which has been arrived at does not show or take into account the reduction of acceleration due to the building up of vibration. Of course, if the vibration is small the difference between the constant-torque case and the constant-acceleration case is also small because the countertorque due to the vibration building up is negligible; hence, the analysis based on constant acceleration should be a good basis for design in the case of constant torque where the amplitude is limited to a small magnitude. In order to estimate when the error due to assuming constant acceleration is important, an approximate calculation of the torque required to maintain constant acceleration has been made. In those cases where the torque is practically constant, the assumption of constant acceleration is evidently justified.

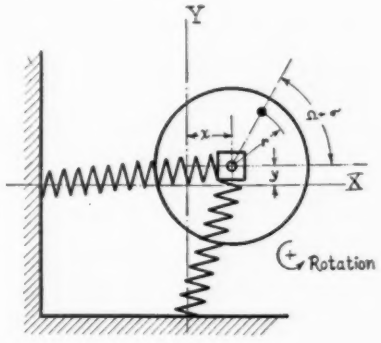

FIG. 1

DETAIL OF SYSTEM ANALYZED AND NOTATION

Fig. 1 shows a spring-mounted rotor movable in a plane perpendicular to its axis. The springs supporting the bearings on which the rotor is mounted are such that displacement of the rotor in

[1] The mathematical machine work was done on the differential analyzer at M.I.T. under the guidance of Prof. S. H. Caldwell with the assistance of J. L. C. Löf. The project as a whole was sponsored by and carried out in cooperation with the Westinghouse Electric & Manufacturing Company.

[2] Vice-President, Baker Mfg. Co., and consulting engineer, Westinghouse Elec. & Mfg. Co., and Hamilton Standard Propellers.

[3] A similar problem in which a vibrating system is disturbed by a constant amplitude force of changing frequency instead of an unbalance (with which the force amplitude varies approximately with the square of the frequency) has been solved exactly without the aid of a mathematical machine and was given in the article: "Vibration During Acceleration Through a Critical Speed," by F. M. Lewis, Trans. A.S.M.E., vol. 54, 1932, paper APM-54-24, p. 253.

[4] For a complete description see "The Differential Analyzer, a New Machine for Solving Differential Equations," by V. Bush, *Journal of The Franklin Institute*, vol. 212, October, 1931, p. 447.

[5] No distinction need be made between a spring-mounted rotor and a spring-mounted reciprocating machine in the discussion. It will be noted, however, that the vibration of a spring-mounted rotor absorbs twice as much energy from the rotating torque as is absorbed by a spring-mounted reciprocating machine, other factors being equal.

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[6] With the new differential analyzer now being constructed at Massachusetts Institute of Technology, it is believed that the solution of the case of constant applied torque can be obtained.

one direction does not produce spring forces perpendicular to the displacement. The spring constant and damping will be considered the same in both x- and y-directions. The means of applying damping is not shown.

In the following notation, the dimensions are indicated by M, L, and T for mass, length and time, respectively; M is also used for the mass of the rotor assembly less the unbalance. Let

M = mass of rotor assembly including mass of all parts moving with rotor except the unbalance $[M]$

m = mass of unbalance $[M]$

d = radius of unbalance $[L]$

K = spring constant in either x- or y-direction $\left[\frac{M}{T^2}\right]$

C = damping constant for either x- or y-direction $\left[\frac{M}{T}\right]$

Ω = angular displacement of rotor in radians from position at which the rotor velocity is zero (dimensionless)

ω = instantaneous angular velocity of rotor in radians per unit time $\left[\frac{1}{T}\right]$

ω_0 = instantaneous frequency of rotor lateral motion in radians per unit time $\left[\frac{1}{T}\right]$

t = elapsed time $[T]$

t_1 = time at which angular velocity is zero for deceleration $[T]$

σ = phase angle of unbalance in radians when rotor velocity is zero [dimensionless]

I = moment of inertia of rotor including the unbalance $[ML^2]$

v = displacement of unbalance m in x-direction $[L]$

h = acceleration of rotor in cycles per unit time per unit time $\left[\frac{1}{T^2}\right]$

T = torque required to produce specific acceleration $\left[\frac{L^2M}{T^2}\right]$

T_1 = $2\pi hI$ = torque required to increase angular momentum $\left[\frac{L^2M}{T^2}\right]$

T_2 = torque required to supply vibrational energies $\left[\frac{L^2M}{T^2}\right]$

e = $md/(M+m)$ = eccentricity of center of gravity of rotor $[L]$

E_s = energy stored in system due to vibration $\left[\frac{L^2M}{T^2}\right]$

E_d = energy dissipated by damping $\left[\frac{L^2M}{T^2}\right]$

E_r = $\frac{I\omega^2}{2}$ = energy stored due to rotation

N = $\frac{1}{2\pi}\sqrt{\left(\frac{K}{M+m}\right)}$ natural frequency in cycles per unit time $\left[\frac{1}{T}\right]$

x = displacement of rotor bearing, center to right, Fig. 1 $[L]$.

y = displacement of rotor bearing, center up, Fig. 1 $[L]$.

x_a = amplitude of x during acceleration $[L]$

x_d = amplitude of x during deceleration $[L]$

x_0 = amplitude of x in any case $[L]$

x_{ma} = maximum amplitude of x during acceleration $[L]$

x_{md} = maximum amplitude of x during deceleration $[L]$

x_s = amplitude calculated from constant-speed theory $[L]$

u = x/e; $u_a = x_a/e$; $u_d = x_d/e$; $u_{ma} = x_{ma}/e$; $u_0 = x_0/e$; $u_s = x_s/e$

u_{md} = x_{md}/e; u_m = either u_{md} or u_{ma} (all dimensionless)

q = N^2/h = number of undamped free vibrations there would be in the time interval between rotational-speed zero and rotational frequency equals the natural frequency (dimensionless); vice versa for deceleration

$q/2$ = number of revolutions the rotor makes in time interval between the time when the rotational velocity is zero and the time when the rotational frequency and t. natural frequency are equal [dimensionless]; vice versa for deceleration

γ = $C/\sqrt{K(m+M)}$ = damping constant (dimensionless)

$\frac{1}{\gamma}$ = amplitude of u that would be obtained were there no acceleration and the system was operated at resonance (dimensionless)

β = $\omega/2\pi N$ = ratio of the instantaneous rotational frequency to the natural frequency (dimensionless)

β_p = increment in β for one period of vibration as measured from differential-analyzer chart (dimensionless)

β_a = β for acceleration; $\beta_d = \beta$ for deceleration

β_d = $\frac{-(\tau-\tau_1)\sqrt{2}}{\sqrt{R}}$ (dimensionless)

t_1 = time at which $\beta_d = 0$

Substitutions made for algebraic simplification:

$F = \gamma\sqrt{(\pi q)}$; $\tau = t\sqrt{(\pi h)}$; $\tau_1 = t_1\sqrt{(\pi h)}$

τ_p = increment in τ for one period of vibration $\tau_p = \beta_p\sqrt{\pi q}$

$F = \gamma\sqrt{\pi q}$ for acceleration only $\tau = \beta_a\sqrt{(\pi q)}$

$R = 2\pi q$; for deceleration $(\tau - \tau_1) = -\beta_d\sqrt{(\pi q)}$

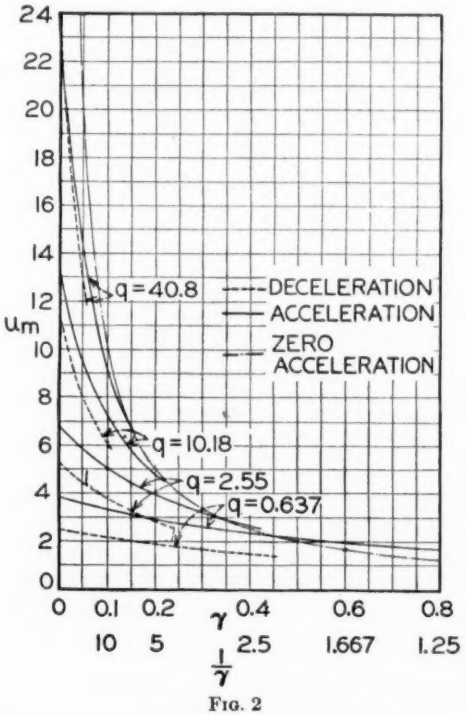

FIG. 2

RESULTS WITH APPLICATION TO SPRING MOUNTINGS

Fig. 2 shows the results as far as maxima are concerned. Figs. 3 and 4 were traced from the curves plotted automatically by the

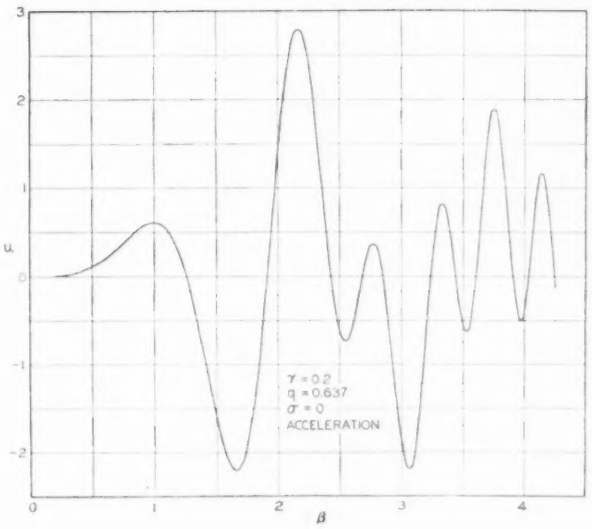

FIG. 3

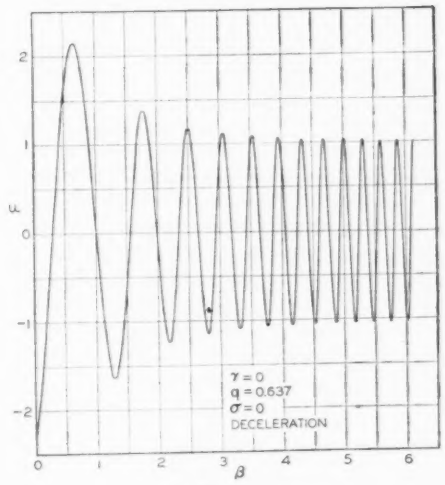

FIG. 4

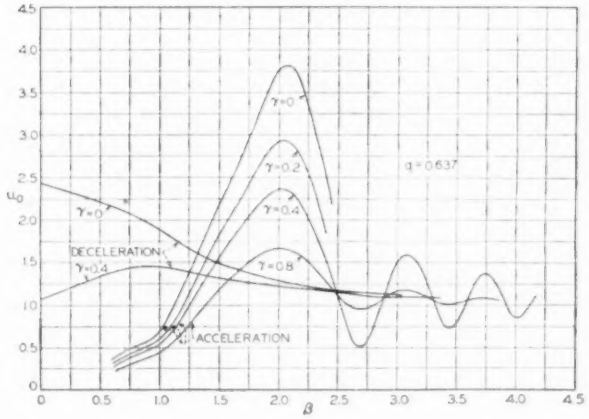

FIG. 5

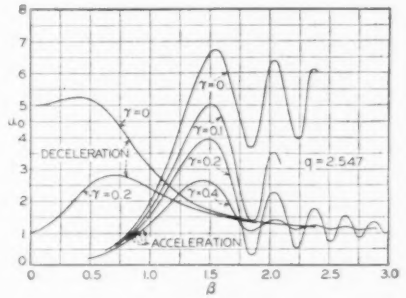

FIG. 6

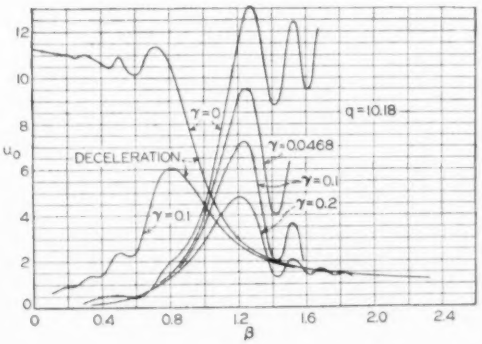

FIG. 7

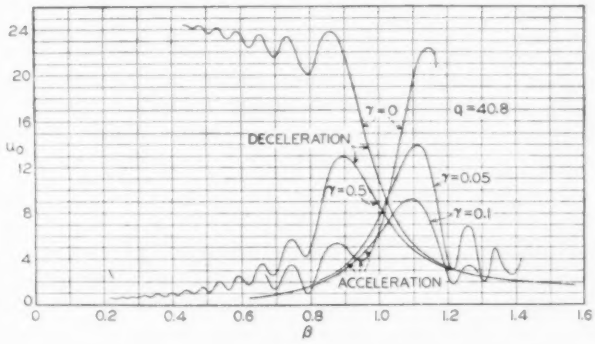

FIG. 8

differential analyzer. They show the displacement as a function of frequency ratio; (u as a function of β). Figs. 5, 6, 7, and 8 show the amplitudes u_0 as functions of frequency ratio β. For each low value of q several values of σ were used to obtain enough points to plot u_m curves.

Fig. 2 shows, not quite directly, the importance of choosing a low spring constant for a spring mounting, where it is desirable to minimize the maximum amplitude attained in coming up to speed with the mass and acceleration of a rotor given. To illustrate, consider two cases, both with the same total mass, $M + m$, and the same acceleration h but with case I with a lower spring constant K_1 than the spring constant K_2 for case II and compare the damping constants C_1 and C_2 in cases I and II, respectively, required to limit the maximum amplitude u_{ma} to the same magnitude in both cases. Let γ_1 and γ_2 be the dimensionless damping ratios for case I and case II, respectively, and let q_1 and q_2 be the respective magnitudes of q. Under these conditions and from the definitions of q and N

$$\frac{K_1}{K_2} = \frac{q_1}{q_2} \quad \text{[1.1]}$$

also from the definition of γ, and from Equation [1.1] and for no change in $M + m$

$$\frac{C_1}{C_2} = \frac{\gamma_1}{\gamma_2}\sqrt{\frac{q_1}{q_2}} = \frac{\gamma_1}{\gamma_2}\sqrt{\frac{K_1}{K_2}} \quad \text{[1.2]}$$

For a specific comparison, let u_{ma} be limited to 3. Take for case I $q_1 = 0.637$, then from Fig. 2, $\gamma_1 = 0.18$. For case II take $q_2 = 2.55$, then also from Fig. 2, $\gamma_2 = 0.33$. From Equation [1.1] $K_1/K_2 = 1/4$, and from Equation [1.2] $C_1/C_2 = 0.273$. In short, in reducing the spring constant to one quarter, the damping constant under the conditions considered can also be reduced to approximately one quarter for the same maximum amplitude of vibration. The amplitude of force on the foundation at speed will be reduced to about one quarter since u is approximately unity at full speed irrespective of the spring constant so long as the natural frequency is low compared to the full-speed frequency.

A comparison may also be made to show the effect of spring-constant reduction on amplitude with a given damping constant. Taking the same values of q_1, q_2, K_1, K_2 as before, then from Equation [1.2]

$$\gamma_1/\gamma_2 = 2 \quad [1.3]$$

For a maximum amplitude for the new case I, u_{ma1} of 3, $\gamma_1 = 0.18$ as before and from Equation [1.3], $\gamma_2 = 0.09$. From Fig. 2 with $q_2 = 2.55$ and $\gamma_2 = 0.09$, $u_{ma2} = 5.15$ or the ratio of the two maximum amplitudes is $u_{ma1}/u_{ma2} = 0.582$. The ratio of the maximum amplitudes of vibratory force will be $u_{ma1}K_1/u_{ma2}K_2$ or 0.146. That is, a reduction in spring constant to one quarter its original value, for the conditions under comparison, reduces the maximum force on the foundation to about one seventh. The frequency of motion at the occasion of the maximum force is also reduced so that the whole effect is made more than proportionally milder by a reduction in spring constant.

Discussion of Errors in the Mathematical-Machine Operation

In the setting up of the machine numerous checks were made of the setup. As a check of the results a comparison can be made between the u_a at frequencies high above the natural frequency and the amplitude as calculated from the ordinary constant-speed theory which u_a would be expected to approach except in the case of no damping where a sustained free vibration might be expected. In expressing the constant-speed solution for frequencies high above the natural-frequency damping, unless it is very large, need not be taken into account so that the amplitude u_s becomes simply

$$u_s = \frac{1}{(1/\beta^2) - 1} \quad [1.4]$$

Of the graphs which were run out far enough to compare with Equation [1.4], discrepancies of about 5 per cent were noted.

Erratic errors are apparently small in the differential analyzer for, in a few instances, parts of runs were repeated with the new line traced by the machine falling on top of the old. Another check was the observation of the accuracy with which the machine generated sine and cosine functions. Many cycles would often be generated with less than 1 per cent error as observed by changing amplitude. In the runs evolving many cycles, corrections were introduced at the shafts generating sine and cosine functions in order to minimize accumulated error. In one case ($q = 2.547$; $\gamma = 0$) two runs were made, one with these corrections and one without. At the maximum amplitude the run without the corrections gave 1.5 per cent higher value than with the corrections. Further along for β about 3 the difference was 4 per cent at the peaks; however, except at the peaks the curves were identical as far as could be detected.

In another check it was noted that the maxima, for runs differing only in the value of the phase σ used, all plotted on a single smooth curve; for large values of q only one value of σ was used so that this check could not be made. It is expected that the runs for the smaller q's are more accurate than the runs with larger q's

Derivation of Differential Equation for the Case of Acceleration

The displacement of m with respect to the rotor center will be $d \cos(\Omega + \sigma)$. The total displacement v of m in the x-direction will be

$$v = x + d \cos(\Omega + \sigma) \quad [1]$$

The lateral force to the right, of m on M will be

$$-m\frac{d^2v}{dt^2} = m\frac{d^2x}{dt^2} - md\frac{d^2}{dt^2}(\cos[\Omega + \sigma]) \quad [2]$$

Equilibrium of the disk mass then gives

$$(M + m)\frac{d^2x}{dt^2} + C\frac{dx}{dt} + Kx = -md\frac{d^2}{dt^2}(\cos[\Omega + \sigma]) \quad [3]$$

Carrying out the indicated differentiation in the right-hand member of Equation [3], Equation [3] becomes

$$(M + m)\frac{d^2x}{dt^2} + C\frac{dx}{dt} + Kx = md\frac{d^2\Omega}{dt^2}\sin(\Omega + \sigma) + md\left(\frac{d\Omega}{dt}\right)^2\cos(\Omega + \sigma) \quad [4]$$

Setting $\Omega = t^2\pi h$, which expresses a displacement of uniform acceleration, and introducing the dimensionless parameters defined previously, Equations [3] and [4] become Equations [5] and [6], respectively

$$\frac{1}{2}\frac{d^2u}{d\tau^2} + F\frac{du}{d\tau} + Ru = -\frac{1}{2}\frac{d^2}{d\tau^2}(\cos[\tau^2 + \sigma]) \quad [5]$$

$$\frac{1}{2}\frac{d^2u}{d\tau^2} + F\frac{du}{d\tau} + Ru = \sin(\tau^2 + \sigma) + 2\tau^2\cos(\tau^2 + \sigma) \quad [6]$$

For the purpose of machine solution Equation [5] was selected and put in the form

$$u = -\cos(\tau^2 + \sigma) - 2\int[R\int u d\tau + Fu]d\tau \quad [7]$$

Differential Analyzer Setup for Case of Acceleration[4]

The differential-analyzer mathematical machine is made up of a number of shafts which may be used to connect machine units of several types. One type of machine unit is the "adder," which is a differential gearing arranged so that one shaft rotates through an angle equal to the sum of the angles through which two other shafts rotate. Another type is the "gear train" by means of which one shaft is made to rotate a fixed fraction of the rotation of another shaft. Thus, the function of the gear train corresponds to multiplication by a constant. Another type of machine unit is the "integrator" which is a variable-ratio transmission between a driving shaft of angular displacement s and a driven shaft of angular displacement z. A third shaft of angular displacement w determines the transmission ratio which may be also denoted by w. Fig. 9 is the standard conventionalized diagram for an integrator with the shafts z, s, and w indicated.[4] For a small displacement of s equal to ds the displacement of z will be dz, so from the definition of w

Fig. 9

$$w = \frac{dz}{ds} \quad [8]$$

and

$$\int w ds = z \quad [9]$$

In the differential analyzer used z must be the driven shaft for

mechanical reasons. On this account z is considered the dependent variable.[7]

Fig. 10 illustrates the setup of two integrators corresponding to the differential Equation [10]. The dots in Fig. 10 indicate connections between perpendicular shafts. Thus

$$\frac{d^2\alpha}{ds^2} + \alpha = 0 \quad \ldots\ldots [10]$$

A solution of Equation [10] is

$$\alpha = \sin(s + \phi) \quad \ldots\ldots [11]$$

where ϕ is a boundary condition. Equation [10] may be written

$$\alpha = -\int\int \alpha\, ds ds \quad \ldots\ldots [12]$$

In Fig. 10, taking the displacements of shaft b and shaft c as s and α, respectively, then integrator III will cause shaft d to rotate an

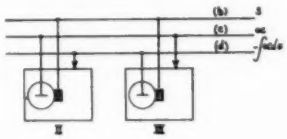

FIG. 10

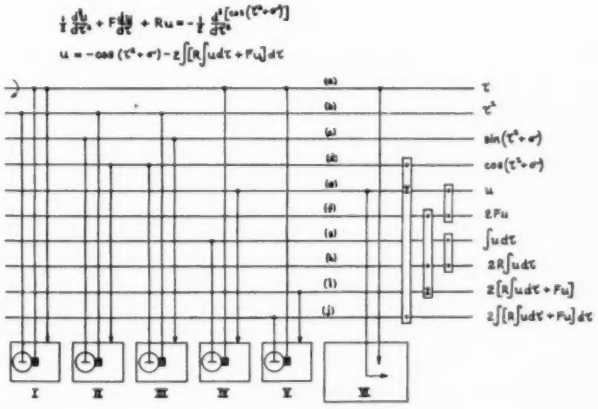

FIG. 11

amount $\int \alpha ds$. Because of the connection to integrator II through a reverse gear, shaft c will rotate $-\int\int \alpha\, ds ds$. Since c must rotate an amount equal to both α and $-\int\int \alpha\, ds ds$ Equation [12] is satisfied by the setup and the motion of c can be $\sin(s + \phi)$ (from Equation [11]) provided the starting conditions are properly selected. If the displacement of c is $\sin(s + \phi)$ then the displacement of d, which is $-\int \alpha ds$, must be $\cos(s + \phi)$.

Fig. 11 shows the setup for Equation [7]. To the displacement of the shaft a is assigned the letter τ. The integrator I performs the operation $\int \tau d\tau$ so that in conjunction with a 2:1 gear shaft b moves an amount τ^2. The arrangement of the integrators II and III and the shafts b, c, and d is, as has already been described, in connection with Fig. 9 (the letter and number indications are the same on the two figures) and Equations [10], [11], and [12]; hence, if s and ϕ are taken equal to τ^2 and σ, respectively, the displacements of c and d indicated on Fig. 11 are accounted for. The displacement of shaft e is taken as u. By means of a gear train of ratio $2F$ connecting e and f (indicated by a small rectangle with two dots) f moves an amount $2Fu$. The integrator IV because of its connections to a and e moves g an amount $\int u d\tau$. Shaft h is driven an amount $2R\int u d\tau$ through a gear train of ratio $2R$ connected to g. Shaft i moves $2[R\int u d\tau + Fu]$ because of the adder connecting f and h to it (indicated by a rectangle with dots at f and h, the displacements of which are to be added, and a summation sign at i the displacement of which is to be the sum of the displacements of f and h). Integrator V moves j $2\int [R\int u d\tau + Fu] d\tau$ due to its connection to i and a. Another adder causes the displacement e to be the sum of the motion of d and j. This addition is expressed by Equation [7] so that with starting conditions of the differential-analyzer machine corresponding to the boundary conditions of the problem rotation of e will be a measure of u which is the result sought. For the case of acceleration τ, u, and $du/d\tau$ are initially zero and σ may be assigned any value. These conditions fix the starting position of all shafts.

The shafts a and e are connected to the plotting mechanism VI. The curve appearing on VI thus has τ for an abscissa and u for an ordinate. The curves of Figs. 3 and 4 were traced directly from such curves. (The τ variable has been exchanged for β.)

Analysis and Differential-Analyzer Setup for the Case of Deceleration

The case of deceleration is taken as that in which the rotor is initially operating at a speed far above its natural frequency and decelerating at a uniform rate. It is assumed that no appreciable free vibration is present at this time. As with the case of acceleration, constant deceleration has been assumed instead of constant retarding torque.

Equations [3] and [4] still hold in the case of deceleration but Ω must no longer be set equal to $t^2\pi h$. If the rotor is rotating rapidly and slowing down, then if its velocity is negative

$$\frac{d^2\Omega}{dt^2} = 2\pi h \quad \ldots\ldots [13]$$

If $t = t_1$ when $\frac{d\Omega}{dt} = 0$ and $\Omega = 0$, then

$$\frac{d\Omega}{dt} = 2\pi h(t - t_1) \quad \ldots\ldots [14]$$

or

$$\Omega = \pi h(t - t_1)^2 \quad \ldots\ldots [15]$$

So that if in the equations for acceleration τ^2 is replaced by $\tau - \tau_1{}^2$ the equations for deceleration are obtained; thus, Equation [5] would be changed to

$$\frac{1}{2}\frac{d^2u}{d\tau^2} + F\frac{du}{d\tau} + Ru = -\frac{1}{2}\frac{d^2}{d\tau^2}(\cos[(\tau - \tau_1)^2 + \sigma]) \quad \ldots [16]$$

where τ_1 has a large value. Since the initial speed will be far above the natural frequency the ordinary constant-speed solution neglecting damping would be expected to give a good approximation of the initial amplitude. On this basis, Equation [16] may be approximated for frequencies high above the natural frequency as

$$\frac{1}{2}\frac{d^2u}{d\tau^2} + Ru = 2[\tau - \tau_1]^2 \cos([\tau - \tau_1]^2 + \sigma) + \sin([\tau - \tau_1]^2 + \sigma) \quad \ldots [17]$$

For τ_1 large compared to τ Equation [17] becomes

$$\frac{1}{2}\frac{d^2u}{d\tau^2} + Ru = 2(\tau_1{}^2 - 2\tau_1\tau)\cos(\tau_1{}^2 - 2\tau_1\tau + \sigma) \quad \ldots [18]$$

[7] In order to obtain accuracy of transmission ratio and to avoid large torques in the w shaft, no appreciable power can be supplied by the z shaft as it leaves the transmission. The necessary power is supplied to a z' shaft not directly connected to the z shaft. Just sufficient torque is supplied to the z' shaft to make it move with the z shaft. The torque supplied is controlled by minute relative displacement between the z and z' shafts. Because z and z' move practically together no distinction will be made between their displacements.

Furthermore the $-2\tau_1\tau$ may be neglected in the coefficient of the cosine term because it is small compared to τ_1^2. However, $-2\tau_1\tau$ may not be neglected under the cosine sign because here even though τ_1^2 is extremely large the value of the cosine function is markedly affected. Equation [18] may then be further simplified to

$$\frac{1}{2}\frac{d^2u}{d\tau^2} + Ru = 2\tau_1^2 \cos(\tau_1^2 - 2\tau_1\tau + \sigma) \quad [19]$$

The steady-state solution of Equation [19] is

$$u = 2\tau_1^2 \cos(\tau_1^2 - 2\tau_1\tau + \sigma) \quad [20]$$

$$\frac{du}{d\tau} = -\frac{4\tau_1^3 \sin(\tau_1^2 - 2\tau_1\tau + \sigma)}{R - 2\tau_1^2} \quad [21]$$

Equations [20] and [21] were used to calculate the boundary conditions for the deceleration runs. For simplicity the part of the cycle was chosen where

$$\frac{du}{d\tau} = 0 \quad [22]$$

and therefore where

$$u = \frac{2\tau_1^2}{R - 2\tau_1^2} \quad [23]$$

The differential analyzer set was the same as for acceleration with these boundary conditions and considering that the variable τ is replaced by the variable $\tau - \tau_1$, which starts out with a large negative value ($\tau = 0$). Fig. 4 is typical of the solutions obtained in this way. It will be noted that there is no perceptible free vibration transient at the highest β where the solution started. In cases including damping, slight free-vibration transients were recorded which might be expected since damping was neglected in estimating the boundary condition. However, the presence of damping removed the transient after a few cycles so that the neglect of damping in estimation of the boundary condition is justified.

Torque Required to Accelerate Rotor

The energy equation of the system may be used to calculate approximately the torque required to accelerate.

For a nonrotating mass equally sprung in both directions and vibrating in a circular path, one half of the stored energy is kinetic and one half is potential (elastic energy in springs). The total stored energy may therefore be considered twice the elastic energy or

$$E_s = Ke^2u^2 \quad [24]$$

The energy stored per unit time is

$$\frac{dE_s}{dt} = 2Ke^2u_0\frac{du_0}{dt} \quad [25]$$

The energy dissipated by damping is per unit of time

$$\frac{dE_d}{dt} = C\omega_0^2x_0^2 = C\omega_0^2u_0^2e^2 \quad [26]$$

If the vibrating mass is rotating and being accelerated, the energy due to rotation is $I\omega^2/2$ and the increase in rotational energy per unit time will be

$$\frac{dE_r}{dt} = I\omega\frac{d\omega}{dt} = I\omega 2\pi h \quad [27]$$

The only source of energy is the external torque so that equating the energy supplied per unit time to the total energy stored plus the energy dissipated

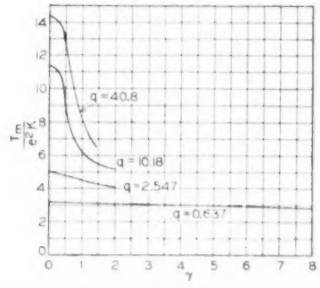

FIG. 12

$$T\omega = 2Ke^2u_0\frac{du_0}{dt} + C\omega_0^2u_0^2e^2 + I\omega 2\pi h \quad [28]$$

or

$$T_2 = \frac{C\omega_0^2u_0^2e^2}{\omega} + \frac{2Ke^2u_0}{\omega}\frac{du_0}{dt} \quad [29]$$

or introducing nondimensional notation

$$\frac{T_2}{e^2K} = \frac{u_0}{q\beta}\left[\frac{\gamma u_0}{\beta_p^2 q} + \frac{1}{\pi}\frac{du_0}{d\beta}\right] \quad [30]$$

Which is an approximate expression, because the rotor's path was assumed to be a circle, whereas it is actually a complicated spiral. Values of u_0, β_p, and $du_0/d\beta$ were obtained from the charts drawn by the differential analyzer and T_2/e^2K calculated from the approximate Equation [30]. The results are plotted in Fig. 12.

Some Applications of Photoelasticity in Turbine-Generator Design

By M. HETÉNYI,[1] EAST PITTSBURGH, PA.

This paper deals with three particular problems in turbine-generator design, namely (*a*) stress concentrations in transverse grooves of two-pole generator rotors, (*b*) centrifugal stresses in rotors, and (*c*) stress concentrations in T-heads (bolts and blade fastenings). The connection between these problems is only their mutual sphere of application and the fact that in each case the solution has been obtained by photoelasticity. The problems have been investigated as two-dimensional ones, the first and third being analyzed by the standard photoelastic technique, while in the second problem the fundamentally three-dimensional method of "freezing" the stresses in bakelite samples was applied.

Stress Concentration in Transverse Grooves of Two-Pole Generator Rotors

IN A two-pole generator the flexural rigidity of the rotor varies from a maximum value in the pole axis to a minimum value in the winding axis. This unequal rigidity in the two principal axes results in a variation in the static deflection of the rotor as it rotates. The variation in the deflection occurs at a frequency equal to twice the frequency of rotation and results under certain circumstances in an objectionable vibration of the rotor.

The most effective way of preventing the occurrence of this double-frequency vibration is to equalize the flexural rigidity of the rotor in the two principal planes, specifically to reduce the rigidity in the pole axis until it is essentially the same as the combined rigidity of the rotor teeth and field coils in the winding axis. The required reduction in rigidity can be obtained most effectively by cutting segment-shaped transverse grooves in the pole body in uniform intervals along the axis of the rotor as shown in Fig. 1. In order to obtain sufficient reduction of rigidity with a minimum removal of material, the grooves will have to be shaped as narrow slots, in consequence of which the radius R of the semicircular ends of the grooves becomes very small in comparison to other dimensions, such as the net diameter d of the rotor. Under such circumstances a considerable concentration of stress can be expected at the bottom of the grooves and, though the nominal stresses in the rotor body are always low, the safety of design required a determination of the exact stress conditions existing in such cases, specifically in the design shown in Fig. 1.

The problem has been considered as a two-dimensional one and bakelite plane models were prepared representing in $^1/_8$-in. scale the longitudinal middle section of the rotor through the pole axis and the center of the grooves. In order to establish the effect of the spacing of the grooves c on the amount of stress concentration, the tests were started with only one groove on each side of the sample, which corresponds to a $c = \infty$ spacing. Then the spacing $c = 2a$ (corresponding to the proportions of the actual rotor shown in Fig. 1) with five grooves on each side was investigated. Finally the spacing was reduced to $c = a$ when nine grooves were on each side of the plane model. The values $D/d = 1.31$ and $d/2R = 69.3$ were the same in each case, and all three samples were tested in pure bending. The photoelastic pattern obtained in the edge region of the sample with $c = 2a$ spacing of the grooves is shown in Fig. 2.

The maximum stress at the bottom of the grooves can be expressed as $\sigma_{max} = k\sigma_{nom}$, where $\sigma_{nom} = 6M/td^2$ is the nominal fiber stress in bending the net section of width d and thickness t, and k is the concentration factor. From the tests, the k values given in Table 1 were obtained.

TABLE 1 STRESS-CONCENTRATION FACTORS k OBTAINED FROM TESTS

Spacing $c = \infty$	Spacing $c = 2a$	Spacing $c = a$
$k = 6.25$	End groove, $k = 4.75$	End groove, $k = 4.25$
....	Middle groove, $k = 3.95$	Middle groove, $k = 3.20$

In the rotor design the concentration factors for the middle slots should be used because they are in the region of maximum

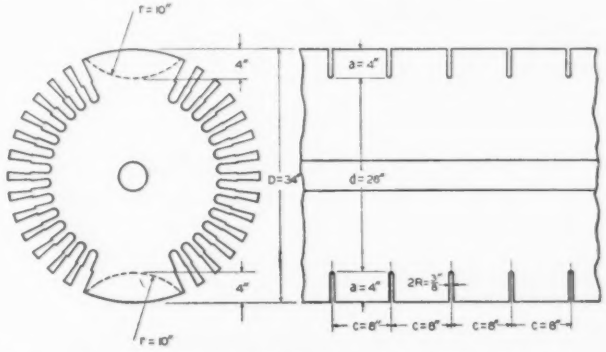

FIG. 1 TWO-POLE TURBINE-GENERATOR ROTOR WITH TRANSVERSE GROOVES IN THE POLE BODY

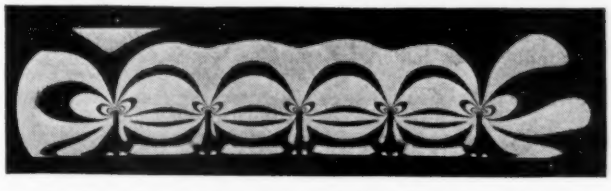

FIG. 2 PHOTOELASTIC PATTERN IN THE EDGE REGION OF A GROOVED SAMPLE IN BENDING

bending stress. Knowing the limiting cases ($c = 0, k = 1$) and ($c = \infty, k = 6.25$) and two other data between, the effect of spacing on the amount of stress concentration can be plotted as shown with the solid curve in Fig. 3. This curve gives the k factor for any middle groove, since the values $D/d = 1.31$ and $d/2R = 69.3$ are kept constant and only the spacing of the

[1] Research Laboratories, Westinghouse Electric & Mfg. Co.

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

grooves changes and shows clearly the stress-relieving effect as the grooves are spaced closer. In comparison with these values, the partial relief of stress which occurs at the end grooves is seen from the numerical data for the k values given in Table 1. In actual generator-rotor design the slot proportions are such that the k factor must always be close to the 3.95 value found for the actual case of an 81250-kva two-pole generator rotor. The ratio $d/2R = 69.3$ gives a bending-stress-concentration factor $k = 7.15$ which, since only one pair of grooves was considered, corresponds also to a $c = \infty$ spacing of grooves. Compared to our test results the k factors for infinitely deep grooves should approach the limiting theoretical value $k = 7.15$ for $c = \infty$ approximately in the manner shown by the dashed curve in Fig. 3.

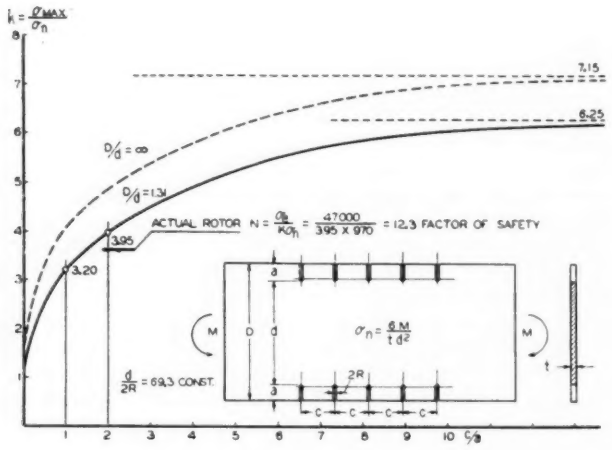

FIG. 3 STRESS-CONCENTRATION FACTOR k FOR TRANSVERSE GROOVES PLOTTED AS A FUNCTION OF THE SPACING OF THE GROOVES

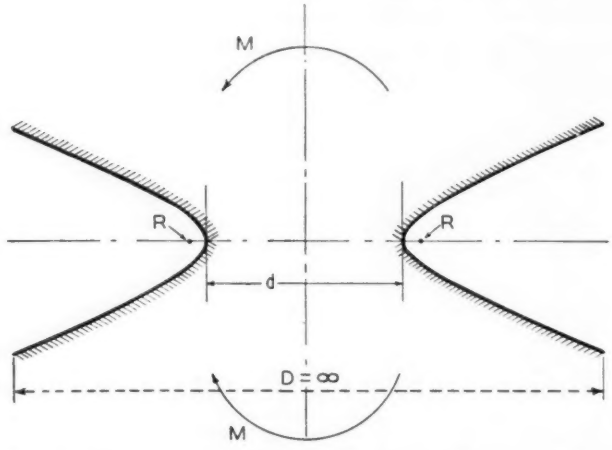

FIG. 4 HYPERBOLIC GROOVES WITH RADIUS OF CURVATURE R AT THE ROOTS, INVESTIGATED THEORETICALLY BY H. NEUBER (1)

nominal stress σ_n for this case is 970 lb per sq in. which multiplied by 3.95 gives a maximum stress of 3800 lb per sq in. The endurance limit of the material σ_e for this case is 47,000 lb per sq in. The factor of safety is $\frac{\sigma_e}{k\sigma_n} = \frac{47000}{3.95 \times 970} = 12.3$, which is well within the standards of accepted design practice and represents a condition of safety equal to or better than that of the regions near ventilation holes and other details encountered in rotor-design practice.

There is no theoretical solution for finite D/d values with which to compare the test results. The only solution of this kind is for the case when $D = \infty$, that is, for an infinitely deep slot of hyperbolic contour line with an R radius of curvature at the root; it was derived by Neuber (1).[2] His formula (2) for a

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

Under the same assumptions as in the plane problem in Fig. 4, Neuber has also obtained a theoretical solution for the corresponding three-dimensional case when the grooves form a surface of revolution. According to his formula (3) in simple bending, the value of maximum stress at the root of such circumferential grooves for $d/2R = 69.3$ and Poisson's ratio $\mu = 0.3$ is $\sigma_{max} = k\sigma_{nom}$, where $k = 6.42$ and $\sigma_{nom} = 32M/\pi d^3$ is the nominal fiber stress in bending of the net section of diameter d.

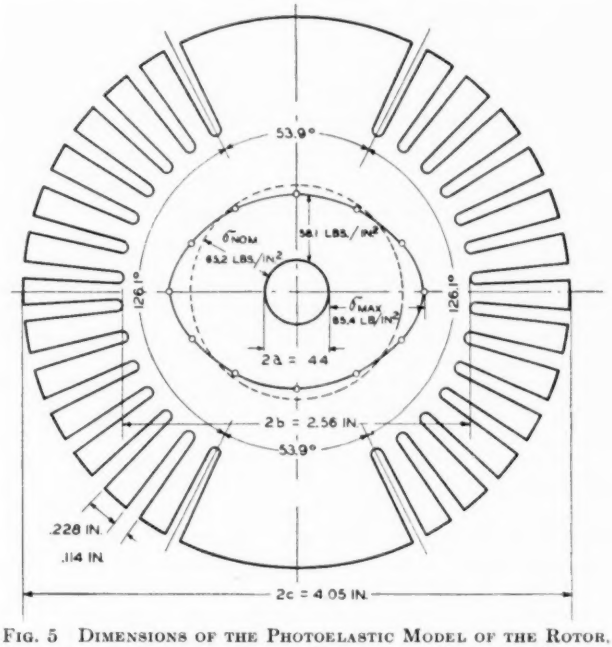

FIG. 5 DIMENSIONS OF THE PHOTOELASTIC MODEL OF THE ROTOR, SHOWING THE DISTRIBUTION OF CENTRIFUGAL STRESSES AROUND THE CORE

It is seen that the concentration factor for the three-dimensional case is about 10 per cent less than for the corresponding two-dimensional problem. On this basis it is justifiable to say that the slightly three-dimensional character of the segmental grooves in our problem, shown in Fig. 1, will cause not more than a few per cent deviation in the value of the factor k obtained from plane model tests.

CENTRIFUGAL STRESSES IN ROTORS

When a sample of heat-hardening resin, such as bakelite BT-61-893 commonly used in photoelastic tests, is annealed in a loaded condition, one obtains a specimen in which the elastic strains and birefringence produced by the loading at the annealing temperature are permanently preserved. This method of solidifying or "freezing" elastic-stress fields has been successfully applied in the investigation of three-dimensional stress problems (4) and can be used in every case where the loading of the model is maintained constant during the annealing process. The stress problem of a body rotating with constant velocity is merely a particular case of that of constant loading, which makes the freezing method directly applicable to problems of this kind. As has been shown in a previous publication by the author (5).

from solidified test pieces it is possible to determine the complete stress distribution, comprising the magnitude and direction of each of the principal stresses at any point of a rotating specimen.

The same method has been applied in the present case to determine the distribution of centrifugal stresses around the core of a two-pole generator rotor. The dimensions of the model, made of bakelite BT-61-893, are shown in Fig. 5. This model, 0.27 in. thick, was rotated in an electric oven at a speed of 3600 rpm at a temperature of 120 C for 1 hr and was then slowly cooled down in about 5 hr to room temperature while the speed of rotation was maintained the same. Since at the annealing temperature the modulus of elasticity of bakelite is greatly reduced and consequently the model undergoes noticeable deformations under the influence of centrifugal forces, particular precautions had to be taken in order to keep the sample in a concentric position while it was being rotated in the oven. For this purpose the rotor model was surrounded by a casing lined with rubber and rotated together with the specimen. Knowing from previous tests (6) the modulus of elasticity of the material at the annealing temperature (E = 1080 lb per sq in.), it was possible to predict the expansion of the model during the test and to provide a corresponding clearance in the casing around the sample. At the beginning of the test the specimen was held by friction at its sides but as the temperature was raised, due to the extension of the model and the reduction of its thickness, this friction on the sides was relieved and from this moment on at the latter part of the test the expanded specimen was guided in its central position by its casing along the circumference. This arrangement was simple and satisfactory and no contact pressure of detectable magnitude took place between the model and the casing.

FIG. 6 ISOCHROMATIC LINES OF CENTRIFUGAL STRESSES IN A GENERATOR-ROTOR MODEL

In the rotor model, the width of the teeth was chosen in such a way as to represent the combined weight of the rotor teeth and windings, the sum of which per unit volume is equivalent to two thirds of the specific weight of the rotor body. Making the model with such proportions, the distribution of centrifugal stresses around the core will be the same as in the actual generator rotor.

The photoelastic picture of the "frozen" model is shown in Fig. 6. By calibrating the material it was found that at the annealing temperature in green light one isochromatic line is equivalent to 12.37 lb per sq in. difference in principal stresses in the specimen 0.27 in. thick. Using this fringe value, the core stresses were obtained from the photoelastic pattern and the resulting stress diagram is shown in Fig. 5.

The experimental results can be conveniently compared to a constant nominal stress value easily obtainable by computation if the extra weight is disregarded in the solid poles of the rotor. Under such assumptions the core stresses can be calculated by considering the inner solid part of the rotor between the radii a and b subjected in addition to its own centrifugal loading to uniformly distributed radial tensile forces along its outer circumference equivalent to the inertia forces due to the combined weight of the rotor teeth and windings. Both of the foregoing cases can be computed by known formulas (7) and their sum, the nominal stress σ_{nom} at the core will be

$$\sigma_{nom} = \frac{3+\mu}{4}\rho\omega^2\left(b^2 + \frac{1-\mu}{3+\mu}a^2\right) + \alpha\frac{2b}{b^2-a^2}\rho\omega^2\int_b^c r^2dr \quad \ldots . [1]$$

where a, b, and c are radii, as shown in Fig. 5; μ is Poisson's ratio; ω is the angular velocity; ρ is the mass per unit volume of the material of the rotor; and α is the ratio of the combined weight of rotor teeth and windings per unit volume to the specific weight of solid rotor body. In the photoelastic test we had a = 0.220 in., b = 1.280 in., c = 2.025 in., μ = 0.5, ω = 376.8 sec^{-1}, ρ = 0.000128 lb-sec^2 in.$^{-4}$, and α = $^2/_3$ which, when substituted into Equation [1] give σ_{nom} = 24.40 + 40.80 = 65.20 lb per sq in. Referring the maximum core stress obtained in the test to this calculated nominal stress value, we obtain a stress-concentration factor k = 85.40/65.20 = 1.13 as a result of the extra weight in the poles which was not considered in the calculation.

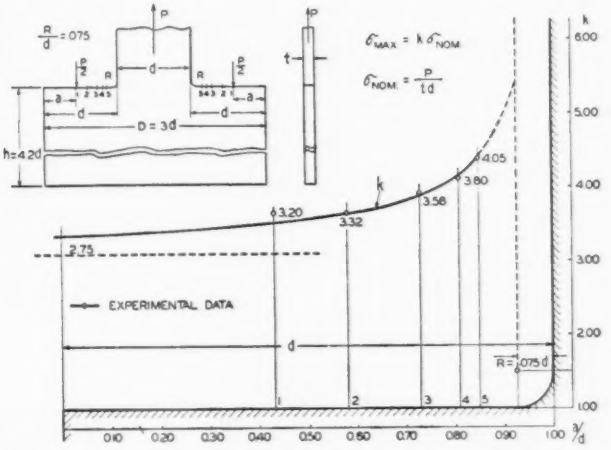

FIG. 7 EFFECT OF THE PROXIMITY OF SUPPORTS TO THE FILLET ON THE STRESS CONCENTRATION IN T-HEADS

The stress increase at the bore due to nonsymmetry of the rotor is thus shown to be negligible as judged from conventional design practice.

STRESS CONCENTRATION IN T-HEADS

T-heads have frequent application in machine design as bolt heads, turbine-blade roots, and various types of fastenings. Tests of such elements have revealed that the stress concentra-

tion at the fillets is usually much greater than what one could expect from a comparison with known results obtained with tension and bending specimens of similar fillet ratios. This fact pointed to the necessity of a more fundamental study of the stress conditions in T-heads which would establish the effect of proportions and other factors on the resulting stress concentration. A partial result of such a study will now be discussed.

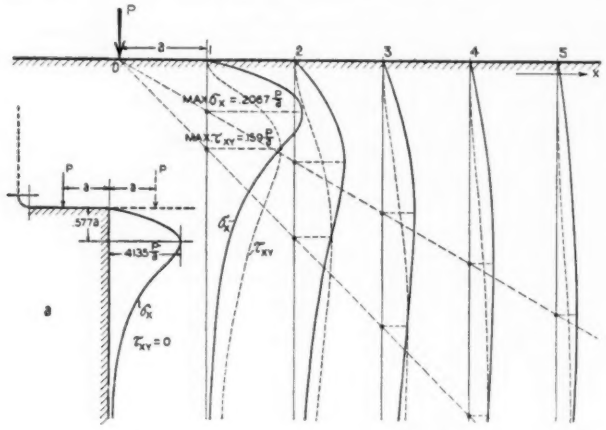

FIG. 8 STRESSES IN A SEMI-INFINITE PLATE DUE TO A CONCENTRATED FORCE

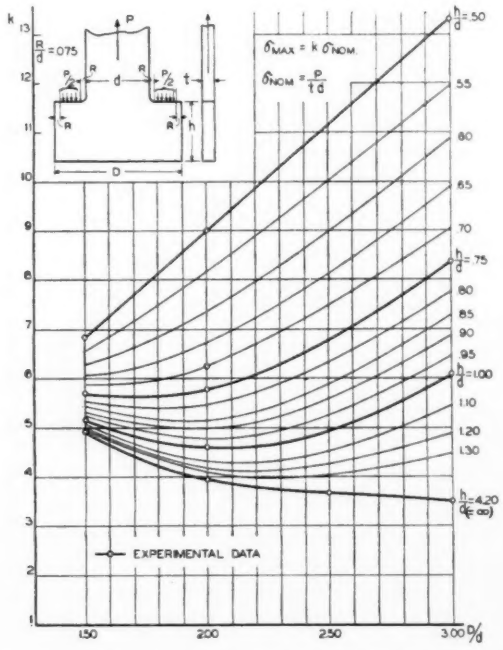

FIG. 9 STRESS-CONCENTRATION FACTOR FOR T-HEADS WITH A CONSTANT FILLET RATIO OF $R/d = 0.075$

Photoelastic tests have been made with T-head models supported along their flanges and subjected to an axial pull P in their center line. The ratio of the fillet R to the width of the mass d was kept constant $R/d = 0.075$ in these tests while other proportions of the head were varied. The maximum stress σ_{max} occurring in the fillet at the junction of the head and the neck can be conveniently expressed as a multiple of the nominal tensile stress in the neck section $\sigma_{nom} = P/td$. Thus $\sigma_{max} = k\sigma_{nom}$, where k is the stress-concentration factor. It was observed in the tests that there were three main factors which contribute to the increase of σ_{max}, namely (*a*) the proximity of the points of support to the fillets, (*b*) the proximity of the edges of the head to the points of support, and (*c*) the bending of the flanges of the head. The influence of these three factors will be discussed separately in the following.

The effect of the proximity of the points of support to the fillets is shown in Fig. 7. A model was tested with the ratios $D = 3d$, $R = 0.075d$ and with such large depth of the head $h = 4.20d$ that the bending of the flanges could be disregarded. This sample was supported at concentrated points successively in positions 1, 2, 3, 4, and 5, and in each case the amount of stress concentration at the fillet was determined. The result of this test series is shown in Fig. 7. It is seen that the concentration factor k rapidly increases as the points of support approach the fillets. It was not advisable to approach the fillets beyond the point No. 5 since the material underwent a considerable distortion in the neighborhood of the concentrated supports and if they were placed close to the fillets, the region of maximum stress could have been also in the yielding region leading to a false reading of σ_{max}. For this reason the value of k in the immediate neighborhood of the fillet was determined by extrapolation. The $k = 2.75$ value is for the case when the sample of $D/d = 3$ and $R/d = 0.075$ ratios is subjected to simple axial

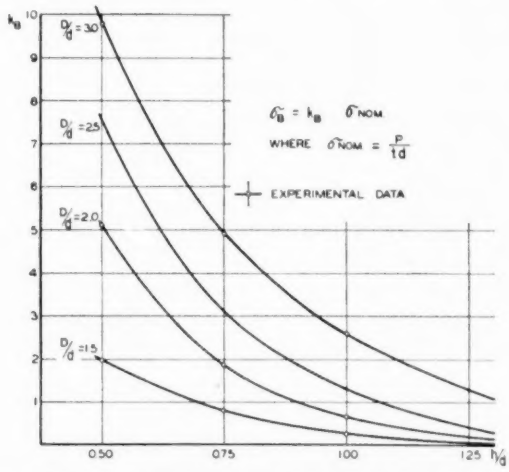

FIG. 10 EFFECT OF BENDING OF SHOULDERS, SEPARATED FROM FIG. 9

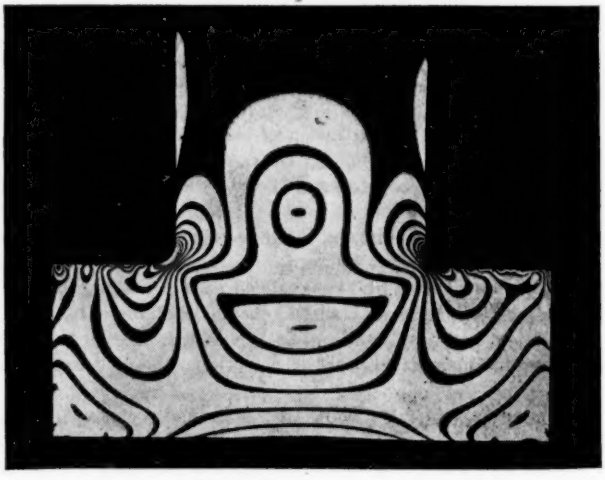

FIG. 11 PHOTOELASTIC PATTERN OF A T-HEAD SUBJECTED TO AN AXIAL PULL AND UNIFORMLY SUPPORTED ALONG THE FLANGES

FIG. 12 ISOCHROMATIC LINES AT THE FILLETS OF THE T-HEAD SHOWN IN FIG. 11

tension and it is believed that this value corresponds to the imaginary case when the same sample is supported at the flanges at points in infinity. It is seen that if the concentrated supports are exactly at the start of the fillets, the produced stress concentration might amount to about twice the value of that obtained from simple tension specimens of similar dimensions.

When the sample is supported at points Nos. 5 and the width of the head is reduced from $D = 3d$ to $D = 1.5d$, the concentration factor $k = 4.05$, shown in Fig. 7, will increase to a value of $k = 5.10$. This indicates the effect referred to previously as the second factor in the increase of stress concentration, namely, the proximity of the edges of the head to the points of support. A qualitative explanation of this effect can also be obtained from theoretical considerations. When a semi-infinite plate is subjected to a concentrated force P at its straight boundary, the distribution of the normal and shearing stress σ_x and τ_{xy} originated in the vertical sections at various distances from the point of application of the load is shown in Fig. 8. The action of cutting the plate through any of these vertical lines would be equivalent to superposing the negative value of the σ_x and τ_{xy} stresses along the same line which would create there a free unloaded vertical boundary. The τ_{xy} shearing stresses can be removed by applying another force P symmetrically on the other side of the vertical section, doubling thereby the compressive normal forces σ_x along the same line as shown in Fig. 8*a*. Thus the action of cutting can be considered as superposing σ_x tensile forces of this double intensity on the stress conditions existing in the case shown in Fig. 8*a*. It is seen from Fig. 8 that if a is small, that is, if the vertical section is close to the point of application of the load, then the σ_x stresses used for producing the free boundary at that place will be of considerable magnitude. Their maximum will be right under the surface so that they will be apt to increase substantially the tensile stresses in the fillet which is assumed to be not far away on the other side of the point of support shown in Fig. 8*a*. As a physical picture, the action of the σ_x tensile stresses can be also conceived as "shearing off" the flanges at an oblique angle sloping outward, which is easy to realize in the case when the points of support are close to the edges of the head.

The last factor, the bending of the flanges, was investigated in a series of tests, starting for every D/d value with a large depth of the head ($h = 4.20d$) and successively reducing the depth h, increasing thereby the bending stresses in the flanges. In these tests the support of the specimens was provided by uniformly distributed reaction forces extending to one fillet-radius distance toward the ends of each flange as shown in Fig. 9. It was necessary to adopt this type of support in order to eliminate one of the variables, the position of the reaction forces, and to reduce thereby the combinations to be investigated. The system of curves shown in Fig. 9 is the result of this test series for the particular value of fillet ratio $R/d = 0.075$. The bottom curve is obtained for T-heads of large depth ($h = 4.20d \rightarrow \infty$), where the bending action of the flanges was negligible, the successive curves above show the rise of k due to increasing bending while the top curve shows that for $h = 0.50d$ ratios the bending stresses are dominant. The heavy lined curves in Fig. 9 were based on test data shown by small circles. The intermediate curves were determined by graphical interpolation from the curves in Fig. 10 where the effect of bending is separated from the data of Fig. 9 and plotted as a function of h/d. Fig. 11 shows the photoelastic picture of one of the samples tested in the previously mentioned series. The proportions of this specimen were $D/d = 2.00$, $h/d = 0.70$, and $R/d = 0.075$; the concentration factor was found to be $k = 6.25$. An enlargement of the isochromatic lines at the right-side fillet of this sample is shown in Fig. 12.

A Two-Load Method of Determining the Average True Stress-Strain Curve in Tension

By C. W. MacGREGOR,[1] CAMBRIDGE, MASS.

The author describes a method, developed at the Massachusetts Institute of Technology, whereby the complete average true stress-strain curve in tension may be determined for a material from the beginning of yielding to fracture under ordinary testing speeds by the observation during the test of only two loads applied to a tapered specimen, namely, the maximum and fracture loads. Diameters at various positions along tapered specimens are measured before and after the test, and stress and reduction-of-area values computed from these observations.

IT WAS suggested recently[2] that instead of plotting stress versus strain in the usual manner for tensile tests of metals, that the average true stress $s = P/A$ be plotted as a function of the true reduction in area $q' = \log (A_o/A)$, where P, A, and A_o are the instantaneous load, the actual area, and the original area, respectively. The advantages of this method of procedure are fully discussed in the references given and will therefore not be repeated here. It may be mentioned, however, that the reduction in area q' thus defined has a better physical basis than the commonly used $q = (A_o - A)/A_o$, and that numerous tests have shown the s-q' curve becomes a straight line from the point corresponding to the maximum load to fracture, which simplifies the recording and interpretation of data. Further, assuming the volume remains constant during plastic deformation (which is true for many metals strained in this fashion to within about 1 per cent), the q' is the same as the true axial strain $\epsilon = \log (L/L_o)$, where L_o is a small original gage length and L is the new distance between gage points produced by strain. Hence, a further advantage of measuring the diameter and computing the true reduction in area q' is obvious since, during necking down, the average true strain in the axial direction may be determined easily in this manner, whereas by ordinary axial-strain measuring methods it would be difficult.

The Two-Load Method[3]

If a tensile-test piece of mild steel having a uniform diameter is stressed in tension, measurements of the diameter along the length of the bar during the test have shown that after the lower yield point is passed, the diameters decrease practically uniformly along the bar until the maximum load is reached. As the load starts to drop from this maximum value, a local necking develops until the bar finally fractures. The diameters of a certain uniform portion of the bar not immediately adjacent to the necked portion change only elastically as the load drops and, as this change is very small compared to the plastic deformation, the true stress corresponding to the maximum load could have been obtained by measuring this uniform diameter after the test and dividing the area of cross section obtained into the maximum load. In other words, with the exception of the necked-down region, the plastic deformation in the form of a reduced area on the fractured bar is produced by the maximum load acting and no further appreciable change in this is produced after the maximum load is applied.

It was then conceived that if a tapered bar were fractured in the same manner, the maximum load acting during the test would produce, with the exception of a small elastic change as the load drops off, the final reduction in area of each diameter of the tapered bar, excluding the necked-down region as before. It would then be possible to determine the s-q' curve (that is, the true stress versus reduction-in-area curve) or the true stress-strain curve (s-ϵ) for the region from the lower yield point to the maximum load point by merely noting the maximum load during the test and measuring the changes in diameter for a number of sections along the tapered bar after the test piece was fractured. This could be done by scribing a uniform spiral along the bar with a diamond tool as will be discussed later, measuring corresponding diameters before and after test, computing the true stress s from the final diameters and the maximum load, and $q' = \epsilon$ from the relation $\log (A_o/A)$.

For the region of the curve from the maximum-load point to fracture, that is, during necking down, the only point for which the diameter and the corresponding load can easily be determined from measurements after fracture is the last or fracture point. Since, however, it is known from previous tests[2] that the s-q' curve is a straight line from the maximum-load point to fracture, the previously mentioned method may be extended to the determination of the complete curve from the lower yield point to fracture by merely noting one extra load, namely, the fracture load. One difficulty which presents itself immediately, however, is that for a tapered specimen it is not clear which diameter corresponds to the maximum load. It was found that this may be overcome by plotting an s-q' curve from first yielding to fracture, where $s = P_{max}/A$, and A is determined from the various diameters along the bar after fracture. This curve possesses an inflection point at the position on the curve corresponding to the maximum load. Therefore, to obtain the remainder of the actual s-q' curve from the maximum-load point to fracture, it merely entails the drawing of a straight line from the point at fracture determined by the fracture load and area to the inflection point of the (P_{max}/A)-q' curve obtained previously

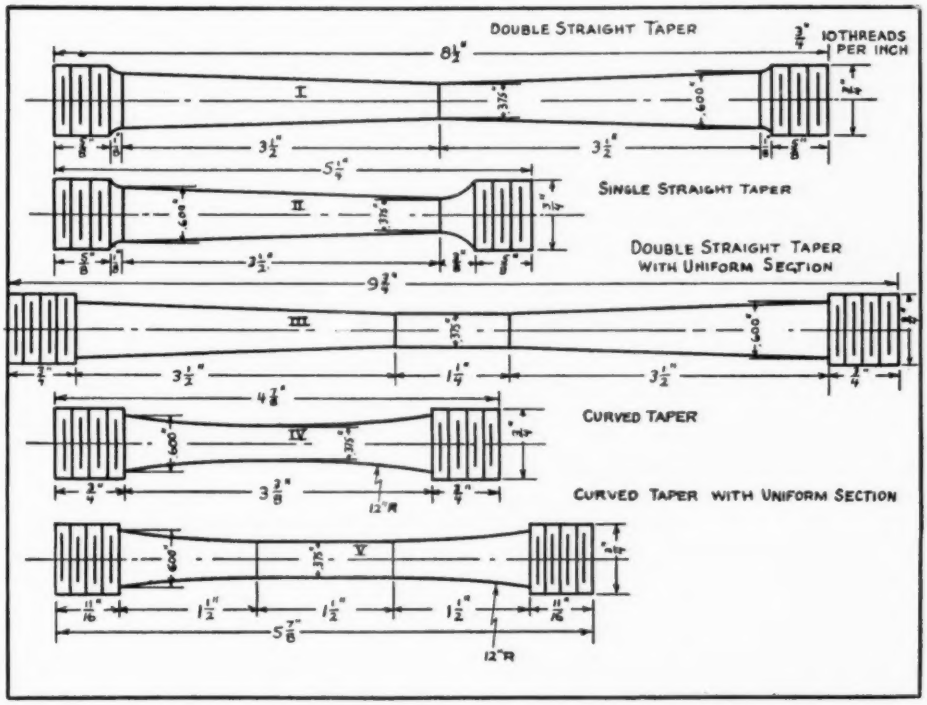

FIG. 1 STRAIGHT AND CURVED TAPERED SPECIMENS USED IN THE TENSILE TESTS

This latter point is not difficult to determine since the actual s-q' curve for a uniform specimen from the beginning of yielding to the maximum-load point will become tangent to the straight line connecting the maximum-load and fracture points.

An experimental program which was carried through to investigate the accuracy of this method will now be described.

EXPERIMENTAL RESULTS

A series of tapered tensile specimens (at least two of each) of types I, II, III, IV, and V shown in Fig. 1 were prepared from fully annealed S.A.E. 1112 steel. These were supplemented by a number of test pieces of the uniform diameters of 0.375 in. and 0.505 in., respectively. After machining, the tapered speci-

mens were polished axially with No. 000 emery paper to remove all toolmarks and to produce scratches in the longitudinal direction only. They were then ruled in a lathe with a continuous spiral scratch produced by a diamond, the axial pitch of the spiral being 0.10 in. These fine rulings were clearly visible against the background of axial scratches produced by the No. 000 emery paper.

The tensile tests were carried out on a Baldwin-Southwark 30-ton hydraulic testing machine. Instead of measuring the axial strain, the reduction in area was determined during the test at the smallest diameter of the tapered specimens by means of a specially designed dial gage and clamp. Corresponding readings of load and minimum diameter were taken to fracture in order to compare these results with those received from the uniform bars.

Referring to Figs. 2 and 3, the solid curves following the points indicated by open circular rings represent the s-q' curves to fracture received from such measurements during the test as described previously on the tapered specimens of types IV and V, respectively. The dashed curves passing through the solid circles are the (P_{max}/A)-q' curve obtained from the maximum load and measurements of final areas along the axes of the tapered specimens after fracture. It will be noted that for type V the s-q' curves for both procedures practically coincide from the lower yield point to the maximum-load point after which they diverge. From Fig. 2 it will be seen that in the case of curved specimen of type IV, the material on either side of the section of minimum diameter produced a slight reinforcing effect. The curves, however, are rather close. It was found that types I and II had an appreciable reinforcing effect and consequently do not give results which compare favorably with the uniform bars. The results of these tests have therefore not been included in this discussion. Type III is difficult to machine and did not give as favorable results as type V. Fig. 4 shows a comparison of the s-q' curves of Figs. 2 and 3, determined by measurements at the minimum diameters for the tapered bars, with that determined on a uniform specimen. The agreement is quite close. It is believed that the specimens of type V are the best suited for this purpose.

Therefore, it will be seen by referring to Fig. 3 that the complete s-q' curve could have been constructed from measurements of the tapered specimen after fracture with the observation of the maximum and fracture loads only. According to this procedure, the dashed curve would first be constructed from measurements of the areas along the specimen after fracture, dividing these final areas into P_{max}, and plotting the curve $0C$ through the solid points so obtained. Point B is also known from the diameter at fracture and the fracture load. From point B then a line would be drawn to the inflection point of $0C$. This line would then represent this portion of the s-q' curve as checked by the measurements shown (the open rings of Fig. 3) on the section of minimum diameter. The only reasons for taking measurements of corresponding load and diameter at the minimum section during the test were to check the reinforcing effect, if any, and to check the described method of construction.

Application of the Method

From the point of view of time required to determine an s-q' or an s-ϵ curve for a given material, at normal temperatures and at ordinary testing speeds, there is little to recommend the two-load method using a tapered specimen as compared to a uniform test piece. More time is consumed in the preparation of a tapered test specimen than for a uniform test bar. If time spent were counted from the beginning of the test, the difference in time required by both methods would not be quite so marked, but probably still in favor of the uniform test bar.

There are, however, cases arising in the testing of materials where it is not practical or feasible to measure the change in diameter of the test bar during the test. Such examples as the determination of s-q' curves at temperatures above room temperature but not high enough to permit appreciable scaling, or the s-q' curve for impact at high velocities, may be mentioned. It is hoped that this method will prove useful in the future when applied to these problems.

Rubber Springs—Shear Loading

By J. F. DOWNIE SMITH,[1] PHILADELPHIA, PA.

The designer in industry should be in a position to predetermine by calculation the size and hardness of, and the deflection to be expected from, a rubber spring which is to serve a special purpose. Unfortunately the literature contains little which would be of help; and it is the author's intention in this paper to supply such information for rubber springs loaded in shear. Most of the designs ordinarily encountered in practice have been considered.

The agreement of theory and experiment is shown in all cases where data are available.

A chart is given which enables anyone to determine immediately the shear angle expected from a plane shear mounting of any size and rubber hardness within the limits ordinarily used for springs.

THE GROWING importance of rubber as a spring material warrants an investigation of the means available for calculating the load-deflection curves for rubber utilized in several possible ways. This present paper is restricted to shear loading of rubber.

The theory involved is developed and the agreement of theory and experimental data is shown graphically for each case studied, where such data are available.

Case 1. Plain Sandwiches

In Fig. 1 the two most common shear rubber springs are pictured. The theory involved is simple. Consider Fig. 1*a*. The modulus of elasticity in shear = G = stress/strain; and stress = W/A.

The definition of strain is set up in engineering literature for small angles either as (*a*) the tangent of the angle, or (*b*) the angle in radians. In the numerous samples tested by the author, and in those cases noted in published experiments, the latter definition gives the better agreement between theory and practice. For that reason it has been adopted in this paper.

Therefore the strain (in radians) = W/AG ..... [1]

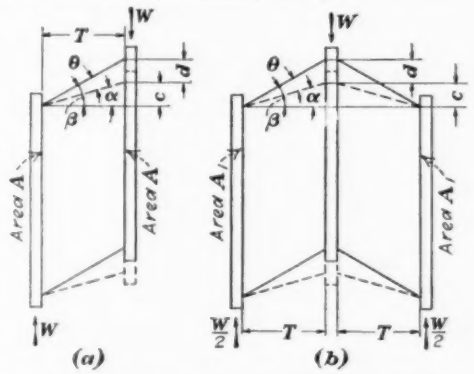

Fig. 1 Two Common Forms of Rubber Shear Springs

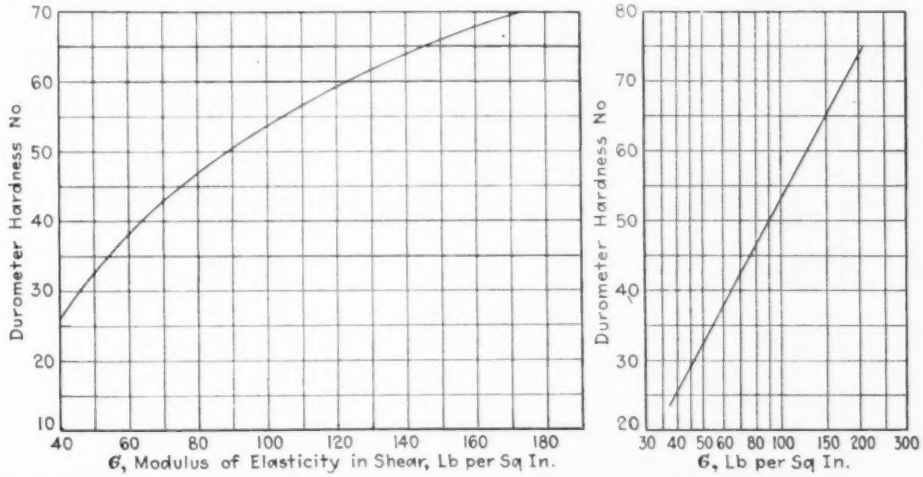

Fig. 2 Relation Between Modulus of Elasticity of Rubber in Shear and Durometer Hardness Number
(The equation of the curve is $G = 16.9e^{D/30.25} = 16.9e^{0.033D}$. The curve should not be extrapolated.)

The strain (in degrees) = $57.3\ W/AG$ ..... [2]

It is then a simple matter to find the deflection d when the original dimensions of the rubber are known. Thus

$$\tan(\theta) = \tan(\beta - \alpha) = (\tan\beta - \tan\alpha)/(1 + \tan\alpha\tan\beta)$$
$$= (d/T)/\{1 + (c/T)[(c + d)/T]\}$$

If θ is in degrees, then

$$\tan(57.3\ W/AG) = (d/T)/\{1 + (c/T)[(c + d)/T]\} \quad \ldots\ldots [3]$$

Ordinarily c/T is small and $(c + d)/T$ is in the order of magnitude of 1 or less. Thus a first degree of approximation can be obtained from

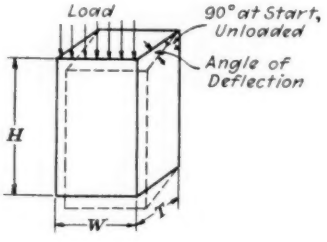
Contributed by the Applied Mechanics Division through the cooperation of Process Industries Division Subcommittee on Rubber and Plastics. Presented at the National Meeting of the Applied Mechanics Division of The American Society of Mechanical Engineers, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.



Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

$$d = T \tan (57.3\ W/AG) \quad [4]$$

If in Fig. 1, $2A_1 = A$, Equations [1] to [4] apply also to the spring of Fig. 1*b*.

From those equations it is possible to calculate the strain or the deflection provided that the physical dimensions of the rubber, the load, and the modulus of elasticity of the rubber in shear are known.

It is common practice to specify the hardness of rubber in terms of an arbitrary scale on a commercially available instrument known as a durometer. It is also possible to correlate the durometer hardness number with the modulus of elasticity in shear, as shown in Fig. 2. The agreement of theoretically derived values and experimental data justifies the conclusion that the durometer hardness number and the shear modulus of elasticity are related in the manner shown to within quite close limits.

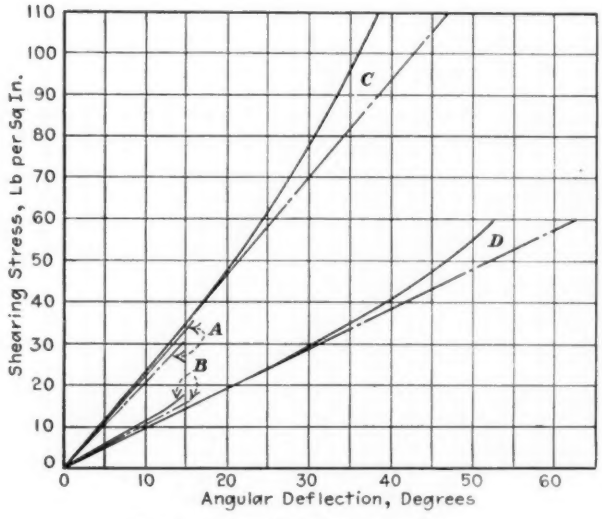


FIG. 3 SINGLE RUBBER SHEAR PADS

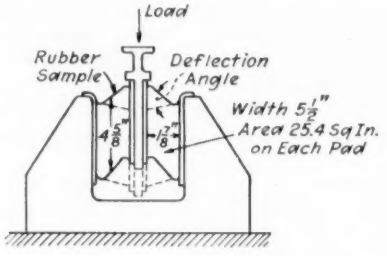
Curves	Dimensions, in. W	T	H	Shear area, sq in.	Durometer number
A	7.87	1.77	3.94	31	58
B	7.87	1.77	3.94	31	38
C	3	3	8	24	60
D	1.2	3/4	3	3.6	35



(Solid lines, experimental curves. Dot-and-dash lines, calculated.)

Unfortunately, it is difficult at present to get two durometers picked at random to agree perfectly, so that for each durometer a curve such as is shown in Fig. 2 is necessary for accurate work. On the other hand, rubber can be obtained from a rubber company with a known durometer hardness number and, from the company's own chart, the modulus of elasticity in shear can be obtained. If necessary, this modulus can be referred to the customer's chart and a durometer hardness number on his own scale obtained. It is regrettable that such a procedure should be necessary.

In Figs. 3 and 4 the close agreement of theory and experiment can be observed, for reasonable angles of deflection, with both single and double shear pads. Fig. 5 is presented to give immediately the angular deflection for any given load and rubber hardness.

Frequently it is necessary to design for greater deflection than can be obtained from a single pair of pads. A double pair is shown in Fig. 6 and a quadruple pair in Fig. 7.

Notice the reasonable check with theory even with the quad-

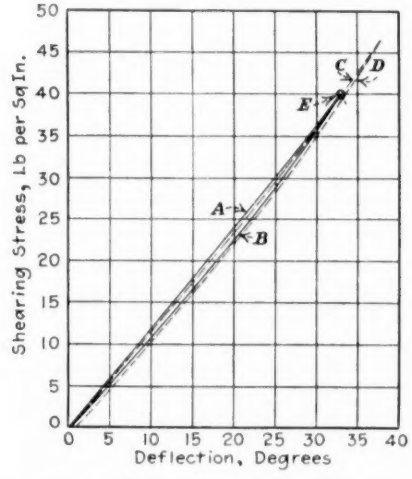


FIG. 4 DOUBLE RUBBER SHEAR PAD

ruple pair, where the metal plates separating the rubber slabs were nowhere near parallel under full load. It would be expected that the greater the number of pads the greater would be the departure from the simple theory outlined. Even with this quadruple pair, however, the error was small.

In the design of such sandwiches it is essential to keep the height large compared with the thickness of the group for the sake of stability. An example of instability due to too small a height-thickness ratio is shown in Fig. 8.

It is customary to supply lateral compression to rubber slabs which are to be loaded in shear. Automatically one would inquire the effect of the compression on the loading curve. Fig. 9 shows that the effect is slight, so that if the angle of deflection is to be calculated the free thickness of the rubber should be used.

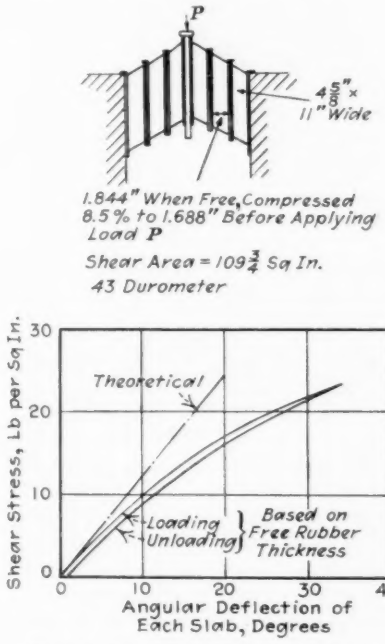

FIG. 8 COMPRESSION-SHEAR LOADING
(Showing instability due to too small a height-thickness ratio. Angular deflections are based on the free thickness of the rubber.)

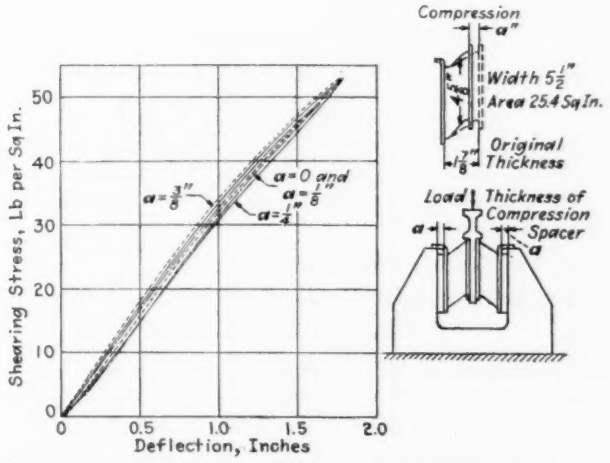

FIG. 9 EFFECT OF DIFFERENT AMOUNTS OF COMPRESSION ON THE LOADING CURVES
(Vertical shearing stress with different amounts of horizontal compression. Room temperature, 75 F; 43 durometer rubber.)

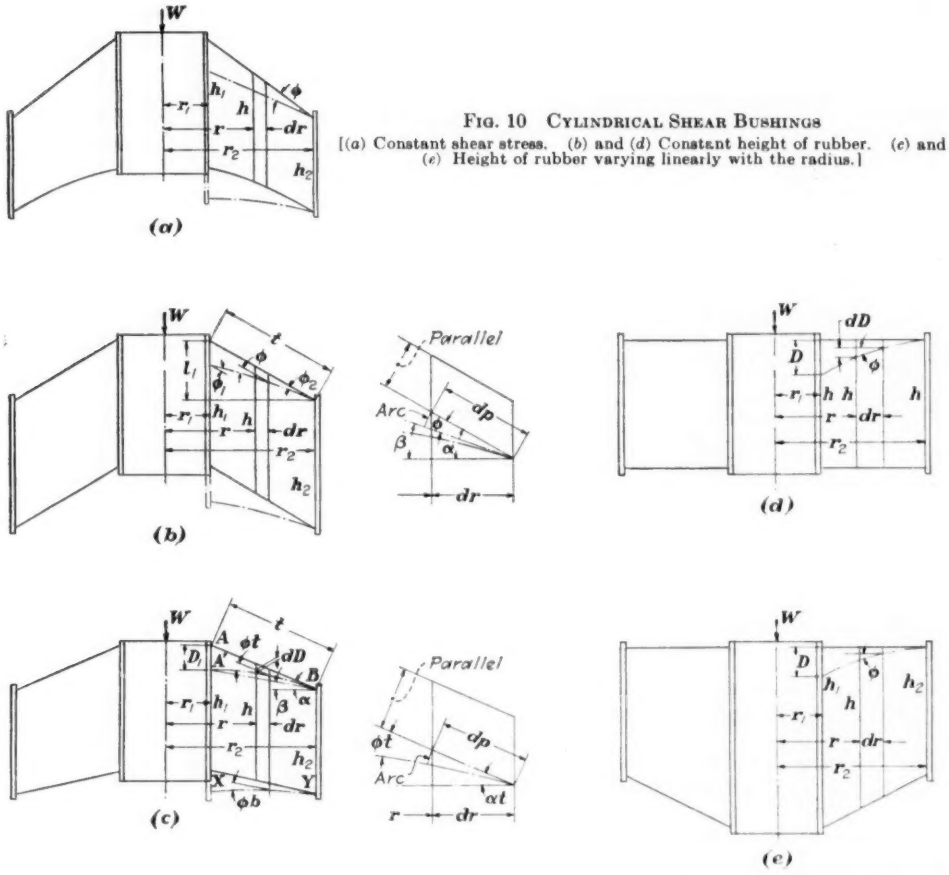

FIG. 10 CYLINDRICAL SHEAR BUSHINGS
[(*a*) Constant shear stress. (*b*) and (*d*) Constant height of rubber. (*c*) and (*e*) Height of rubber varying linearly with the radius.]

The test pieces described so far have all been rectangular. Would the same load-deflection curve be obtained for the same area and rubber hardness if another shape were used? Several different shapes have been tested experimentally and, so long as the thickness of the rubber is appreciably less than the shortest perpendicular length, no great departure from the preceding equations has been found.

CASE 2. CYLINDRICAL SHEAR BUSHINGS

(*a*) ***With Constant Shear Stress, Fig. 10a***

With constant stress, $S/G = \phi = \text{const}$ ..... [5]

$$S = W/2\pi rh = W/2\pi r_1 h_1 = W/2\pi r_2 h_2 \text{ .....} [6]$$

Or, for any load and stress, $rh = \text{const}$ ..... [7]

which is the equation of a hyperbola. Therefore the height should vary inversely as the radius, or $rh = r_1h_1 = r_2h_2$.

The deflection can be obtained from angle ϕ and the physical dimensions of the bushing.

(*b*) ***With Constant Height of Rubber, Fig. 10b***

Here, $h = h_1 = h_2$ and $S = G\phi$. If $W/2\pi h$ is represented by a, then $S_r = a/r$, $S_1 = a/r_1$, $S_2 = a/r_2$.

Therefore the stress varies inversely as the radius.
Now $\phi = S/G = a/rG = b/r$, where $b = a/G$. But $\phi = \text{arc}/dp$ and $dr/dp = \cos\alpha = (r_2 - r_1)/t = g$.

$$\therefore \phi = \text{arc}/dp = \text{arc}(g/dr) \text{ and arc} = (\phi/g)dr = (b/gr)dr$$

$$\therefore \Sigma \text{ arc} = \frac{b}{g}\int_{r_1}^{r_2}\frac{dr}{r} = \frac{b}{g}\log_e\left(\frac{r_2}{r_1}\right)$$

$$= \frac{W}{2\pi hgG}\log_e\left(\frac{r_2}{r_1}\right) = \frac{Wt}{2\pi hG}\frac{\log_e(r_2/r_1)}{(r_2 - r_1)} \text{ .....} [8]$$

Let the angle of movement be θ, then Σ arc $= \theta t$ approximately, and

$$\theta = \frac{W}{2\pi hG(r_2 - r_1)}\log_e\left(\frac{r_2}{r_1}\right) \text{ .....} [9]$$

Another method of solving this problem is to assume that the rubber of the original design of Fig. 10*b* would behave similarly to that shown in Fig. 10*d*.

In this case, $\phi = W/2\pi rhG = b/r$ as before. Roughly, $\tan\phi = dD/dr = \tan(b/r)$.

$$\therefore D = \int_{r_1}^{r_2}\tan\left(\frac{b}{r}\right)dr$$

Now b/r is always less than $\pi/2$.

$$\therefore D = \int_{r_1}^{r_2}\left[\left(\frac{b}{r}\right) + \frac{1}{3}\left(\frac{b}{r}\right)^3 + \frac{2}{15}\left(\frac{b}{r}\right)^5 + \frac{17}{315}\left(\frac{b}{r}\right)^7 + \dots\right]dr$$

$$= b\log_e\left(\frac{r_2}{r_1}\right) - \frac{b^3}{6}\left(\frac{1}{r_2^2} - \frac{1}{r_1^2}\right) - \frac{b^5}{30}\left(\frac{1}{r_2^4} - \frac{1}{r_1^4}\right) - \frac{17b^7}{1890}\left(\frac{1}{r_2^6} - \frac{1}{r_1^6}\right) + \dots$$

$$= b\log_e\left(\frac{r_2}{r_1}\right) + \frac{b^3}{6}\left(\frac{1}{r_1^2} - \frac{1}{r_2^2}\right) + \frac{b^5}{30}\left(\frac{1}{r_1^4} - \frac{1}{r_2^4}\right) + \frac{17b^7}{1890}\left(\frac{1}{r_1^6} - \frac{1}{r_2^6}\right) + \dots$$

$$= \frac{W}{2\pi hG}\log_e\left(\frac{r_2}{r_1}\right) + \frac{1}{6}\left(\frac{W}{2\pi hG}\right)^3\left(\frac{1}{r_1^2} - \frac{1}{r_2^2}\right) + \frac{1}{30}\left(\frac{W}{2\pi hG}\right)^5\left(\frac{1}{r_1^4} - \frac{1}{r_2^4}\right) + \frac{17}{1890}\left(\frac{W}{2\pi hG}\right)^7\left(\frac{1}{r_1^6} - \frac{1}{r_2^6}\right) + \ldots\ldots\ldots [10]$$

(c) With Height of Rubber Varying Linearly With the Radius, Fig. 10c

Here $(h - h_2)/(h_1 - h_2) = (r_2 - r)/(r_2 - r_1)$

$$\therefore h = h_2 + [(h_1 - h_2)/(r_2 - r_1)](r_2 - r) \ldots\ldots [11]$$

Let $a = h_2 + [(h_1 - h_2)/(r_2 - r_1)]r_2$ and $b = (h_1 - h_2)/(r_2 - r_1)$, then $h = a - br$ and

$$\text{strain} = \frac{\text{stress}}{G} = \frac{W}{2\pi rhG}\begin{cases} = \phi_t \text{ at top} \\ = \phi_b \text{ at bottom} \end{cases}$$

$\phi_t = \dfrac{W}{2\pi rG(a - br)} = \dfrac{k}{ar - br^2}$, where $k = \dfrac{W}{2\pi G}$. Now $\phi_t = \text{arc}/dp$, and $dr = dp\cos\alpha_t = dp(r_2 - r_1)/t$

$$\therefore \phi_t = \frac{\cos\alpha_t \text{ arc}}{dr} = \frac{(r_2 - r_1)\text{ arc}}{dr\ t} \ldots\ldots [12]$$

$$\therefore \text{arc} = \frac{\phi_t\ t\ dr}{(r_2 - r_1)} = \frac{t\ k\ dr}{(r_2 - r_1)\ (ar - br^2)} \ldots\ldots [13]$$

$$\therefore \Sigma\text{ arc} = \frac{t\ k}{(r_2 - r_1)}\int_{r_1}^{r_2}\frac{dr}{ar - br^2}$$

$$\frac{r_2 - r_1}{tk}\Sigma\text{ arc} = \int_{r_1}^{r_2}\frac{dr}{ar - br^2} = \frac{1}{a}\log_e\left|\frac{-2br + a - a}{-2br + a + a}\right|_{r_1}^{r_2}$$

$$= \frac{1}{a}\log_e\left(\frac{br}{br - a}\right)\Bigg|_{r_1}^{r_2}$$

$$= \frac{1}{a}\log_e\frac{r_2}{r_1}\left(\frac{br_1 - a}{br_2 - a}\right) = \frac{1}{a}\log_e\frac{r_2h_1}{r_1h_2}$$

$$\therefore \Sigma\text{ arc} = \frac{tk}{a(r_2 - r_1)}\log_e\frac{r_2h_1}{r_1h_2}$$

$$= \frac{tW\log_e(r_2h_1/r_1h_2)}{2\pi G(r_2 - r_1)\left[h_2 + \left(\frac{h_1 - h_2}{r_2 - r_1}\right)r_2\right]} = \frac{tW\log_e(r_2h_1/r_1h_2)}{2\pi G(h_1r_2 - h_2r_1)} \ldots [14]$$

and $\Sigma\text{ arc} = t\theta$ approximately, where θ = total angle of movement.

$$\therefore \theta = \frac{W}{2\pi G(h_1r_2 - h_2r_1)}\log_e\frac{r_2h_1}{r_1h_2} \ldots\ldots [15]$$

This same problem can be handled in a different manner if it is assumed that the top surface of the rubber is a plane surface as shown in Fig. 10*e*, and that rubber of this shape will behave similarly to that shown in Fig. 10c. Here

$\phi = W/2\pi rhG = k/rh$, where $k = W/2\pi G$. Now $h = a - br$,

where $a = \dfrac{h_1r_2 - h_2r_1}{r_2 - r_1}$ and $b = \dfrac{h_1 - h_2}{r_2 - r_1}$

$$dD/dr = \tan\phi = \tan[k/(ar - br^2)]$$

$$\therefore D = \int_{r_1}^{r_2}\tan\left(\frac{k}{ar - br^2}\right)dr$$

Now ϕ is always less than $\pi/2$.

$$\therefore D = \int_{r_1}^{r_2}\left[\frac{k}{ar - br^2} + \frac{1}{3}\left(\frac{k}{ar - br^2}\right)^3 + \frac{2}{15}\left(\frac{k}{ar - br^2}\right)^5 + \frac{17}{315}\left(\frac{k}{ar - br^2}\right)^7 + \ldots\right]dr$$

The integration of this expression is tedious, and the results are complicated. The first two terms alone yield

$$D = \frac{W}{2\pi G}\frac{(r_2 - r_1)}{(h_1r_2 - h_2r_1)}\log_e\frac{h_1r_2}{h_2r_1} \cdot + 2\left(\frac{W}{2\pi G}\right)^3\frac{(h_1 - h_2)^2(r_2 - r_1)^4}{(h_1r_2 - h_2r_1)^5}\log_e\frac{h_1r_2}{h_2r_1} + \frac{1}{6}\left(\frac{W}{2\pi G}\right)^3\frac{(r_2 - r_1)}{(h_1r_2 - h_2r_1)^2}\left[\frac{h_1r_2 - 2r_1h_1 + r_1h_2}{(h_1r_1)^2} + \frac{h_1r_2 - 2h_2r_2 + h_2r_1}{(h_2r_2)^2}\right] + \left(\frac{W}{2\pi G}\right)^5\frac{(h_1 - h_2)(r_2 - r_1)^2}{(h_1r_2 - h_2r_1)^4}\left[\frac{h_1r_2 - 2r_1h_1 + r_1h_2}{h_1r_1} + \frac{h_1r_2 - 2h_2r_2 + h_2r_1}{h_2r_2}\right] \ldots\ldots [16]$$

For a given set of dimensions, however, this expression reduces to

$$D = c_1(W/G) + c_2(W/G)^3 \ldots\ldots [17]$$

which is quite simply used.

(d) With Height of Rubber Varying Linearly With the Radius, Angles α and β Small, Fig. 10c

Assume AB and XY are straight lines at the start. It is desired to obtain

$$\int_{r = r_1}^{r = r_2} dD$$

$$h = b + ar = h_1 + [(h_2 - h_1)(r - r_1)/(r_2 - r_1)]$$

Let $a = (h_2 - h_1)/(r_2 - r_1)$ and $b = h_1 - [r_1(h_2 - h_1)/(r_2 - r_1)]$

$$\phi = \text{Strain} = W/2\pi rhG = W/[2\pi Gr(ar + b)]$$

Let $W/2\pi G = k$, then $\phi = k/(ar^2 + br)$. Now if β is small and α not too large, $dD = dr\phi$

$$\therefore dD = (kdr)/(ar^2 + br) \ldots\ldots [18]$$

$$\therefore D = k\int_{r_1}^{r_2}\frac{dr}{ar^2 + br} = \frac{k}{b}\log_e\left|\frac{2ar + b - b}{2ar + b + b}\right|_{r_1}^{r_2}$$

$$= \frac{k}{b}\log_e\left[\frac{r_2}{r_1}\left(\frac{ar_1 + b}{ar_2 + b}\right)\right] = \frac{k}{b}\log_e\frac{r_2h_1}{r_1h_2}$$

$$\therefore D = \frac{W}{2\pi G\{h_1 - [(h_2 - h_1)/(r_2 - r_1)]r_1\}}\log_e\frac{r_2h_1}{r_1h_2}$$

$$= \frac{W(r_2 - r_1)}{2\pi G(h_1r_2 - h_2r_1)}\log_e\frac{r_2h_1}{r_1h_2} \ldots\ldots [19]$$

Equation [19] is the one proposed by F. L. Haushalter, mentioned by the author in a previous paper.[2]

Fig. 11 shows agreement of theory and practice for a typical bushing.

[2] "Rubber Mountings," by J. F. Downie Smith, *Journal of Applied Mechanics*, Trans. A.S.M.E., vol. 60, March, 1938, p. A-22.

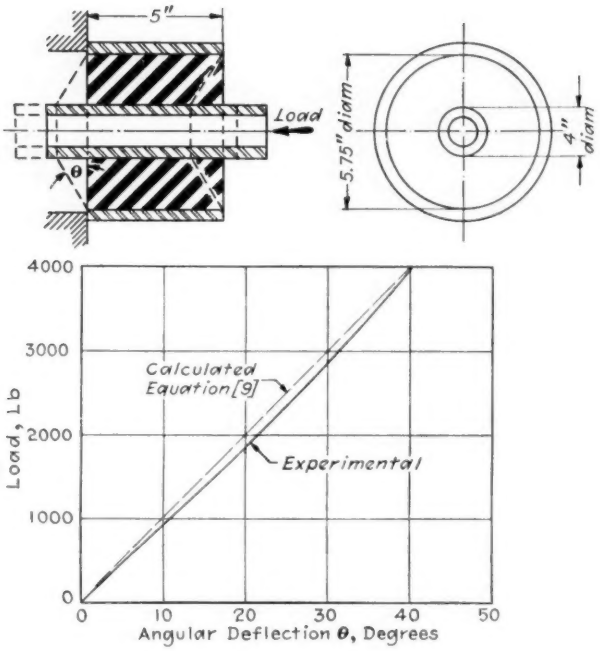

FIG. 11 LOADING CURVES OF CYLINDRICAL SHEAR BUSHING
(Durometer reading, 45.)

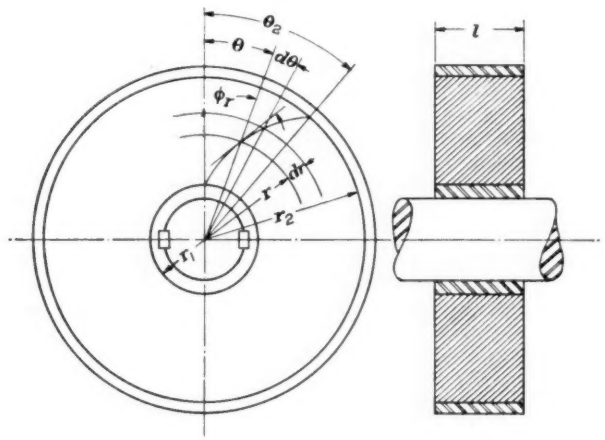

FIG. 12 COAXIAL TUBE OF CONSTANT LENGTH IN TORSION

CASE 3. COAXIAL TUBE OF CONSTANT LENGTH IN TORSION, FIG. 12

$$\text{Torque} = T = 2\pi r^2 lS \quad \ldots\ldots\ldots\ldots\ldots\ldots [20]$$

$$\text{Also, approximately, } r d\theta/dr = \tan \phi_r \quad \ldots\ldots\ldots [21]$$

and $\phi_r = S/G$. $\therefore T = 2\pi l r^2 G \phi_r$

$$\therefore \phi_r r^2 = T/2\pi lG \text{ and } \phi_r = T/2\pi lGr^2 \ldots [22]\ [23]$$

From Equations [21] and [23] $r d\theta/dr = \tan(T/2\pi lGr^2)$

$$\therefore d\theta = (1/r) \tan (T/2\pi lGr^2) dr$$

For a given torque on a given sample, $T/2\pi lG = \text{const} = a$.

$$\therefore \int_0^{\theta_2} d\theta = \int_{r_1}^{r_2} \frac{1}{r} \tan \frac{a}{r^2} dr = \theta_2 \quad \ldots\ldots [24]$$

Let $a/r^2 = t$, or $r = \sqrt{(a/t)}$, then

$$dt = -2ar^{-3}\, dr \text{ and } dr = -a^{1/2} dt/2t^{3/2}$$

$$\therefore \theta_2 = -\int_{r=r_1}^{r=r_2} \left(\frac{t}{a}\right)^{1/2} \tan t \frac{a^{1/2} dt}{2t^{3/2}} = -1/2 \int_{r=r_1}^{r=r_2} \frac{\tan t}{t}\, dt$$

Where $t^2 < \pi^2/4$ the solution of this equation is

$$\theta_2 = -\frac{1}{2}\left[t + \frac{t^3}{9} + \frac{2}{75} t^5 + \frac{17}{2205} t^7 + \ldots \right]_{r=r_1}^{r=r_2}$$

See Dwight's Table of Integrals, No. 481.2

$$\therefore \theta_2 = -\frac{1}{2}\left[\frac{a}{r^2} + \frac{a^3}{9r^6} + \frac{2a^5}{75r^{10}} + \frac{17a^7}{2205r^{14}} + \ldots \right]_{r_1}^{r_2}$$

$$= -\frac{a}{2}\left[\left(\frac{1}{r_2^2} - \frac{1}{r_1^2}\right) + \frac{a^2}{9}\left(\frac{1}{r_2^6} - \frac{1}{r_1^6}\right) + \frac{2a^4}{75}\left(\frac{1}{r_2^{10}} - \frac{1}{r_1^{10}}\right) + \frac{17a^6}{2205}\left(\frac{1}{r_2^{14}} - \frac{1}{r_1^{14}}\right) \ldots \right]$$

$$\therefore \theta_2 = \frac{T}{4\pi lG}\left[\left(\frac{1}{r_1^2} - \frac{1}{r_2^2}\right) + \frac{1}{9}\left(\frac{T}{2\pi lG}\right)^2 \left(\frac{1}{r_1^6} - \frac{1}{r_2^6}\right) + \ldots \right] \quad \ldots\ldots\ldots [25]$$

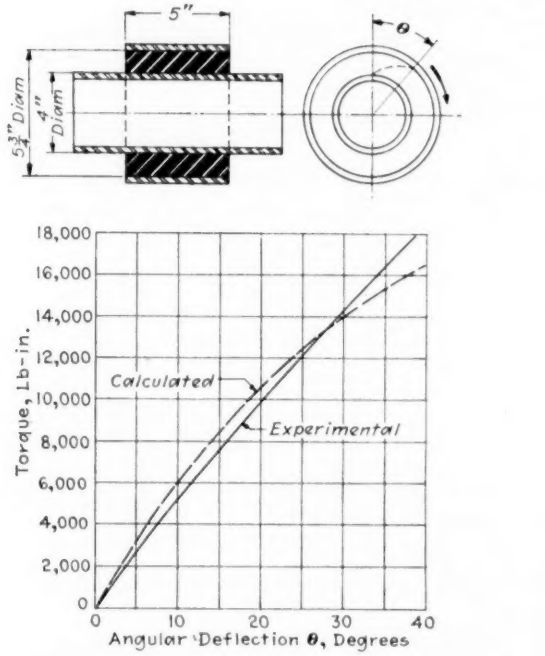

FIG. 13 TORSIONAL LOADING OF COAXIAL TUBE

The solution given in Equation [25] is based on the assumption that $a^2/r^4 < \pi^2/4$, i.e., that $a/r^2 < \pi/2$, that $T/2\pi lGr^2 < \pi/2$, or $\phi_r < \pi/2$ which is ordinarily the case. Therefore the solution is valid.

Fig. 13 shows a typical bushing with both theoretical and experimental curves.

CASE 4. COAXIAL TUBE OF CONSTANT STRESS IN TORSION, FIG. 14

(a) *For Small Deflections*

$$T = (2\pi r \times 2l)Sr = \text{const} = 4\pi r^2 lS \quad \ldots\ldots\ldots [26]$$

$$\therefore r^2 l = T/4\pi S = \text{const} \quad \ldots\ldots\ldots\ldots\ldots [27]$$

which is the equation of a hyperbola.
The stress can be obtained from

$$S = T/4\pi r^2 l = T/4\pi r_1^2 l_1 = T/4\pi r_2^2 l_2 \quad \ldots\ldots [28]$$

For small deflections, $rd\theta/dr = \phi_r$ $\ldots\ldots [29]$

$\phi_r = S/G$

$$\therefore \theta_2 = \int_0^{\theta_2} d\theta = \int_{r_1}^{r_2} \frac{\phi_r}{r}\, dr = \phi_r \log_e \frac{r_2}{r_1} \quad \ldots\ldots [30]$$

$$\therefore \theta_2 \text{ (in radians)} = \frac{S}{G} \log_e \frac{r_2}{r_1} = \frac{T}{4\pi r_2^2 l_2 G} \log_e \frac{r_2}{r_1} \quad \ldots\ldots [31]$$

$$= \frac{2.3026T}{4\pi r_2^2 l_2 G} \log_{10} \frac{r_2}{r_1} = \frac{0.1833T}{r_2^2 l_2 G} \log_{10} \frac{r_2}{r_1} \quad \ldots\ldots [32]$$

$$\theta_2 \text{ (in deg)} = \frac{57.3 \times 0.1833T}{r_2^2 l_2 G} \log_{10} \frac{r_2}{r_1} = \frac{10.5T}{r_2^2 l_2 G} \log_{10} \frac{r_2}{r_1} \quad \ldots [33]$$

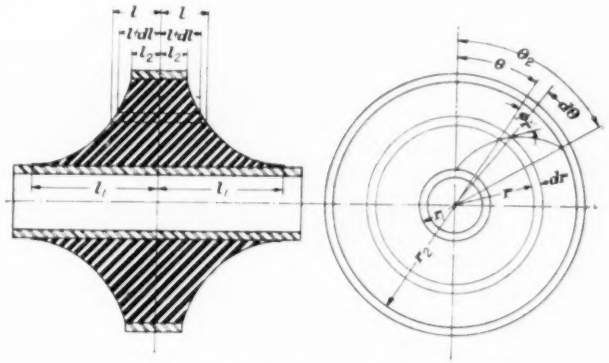

FIG. 14 COAXIAL TUBE OF CONSTANT STRESS

(b) *For Large Deflections, Fig. 14*

$$rd\theta/dr = \tan \phi_r \text{ approximately} \quad \ldots\ldots [34]$$

ϕ_r = strain = S/G = const, $\therefore \tan \phi_r$ = const = a, $\therefore rd\theta/dr = a$

$$\theta_2 = \int_0^{\theta_2} d\theta = \int_{r=r_1}^{r=r_2} \frac{a}{r}\, dr = a \log_e \frac{r_2}{r_1} = \tan \phi_r \times \log_e \frac{r_2}{r_1}$$

$$= \tan S/G \log_e r_2/r_1 \quad \ldots\ldots [35]$$

$$\theta_2 \text{ (in radians)} = \log_e \left(\frac{r_2}{r_1}\right) \tan \left(\frac{T}{4\pi G r_2^2 l_2}\right) \quad \ldots\ldots [36]$$

$$= 2.3026 \log_{10} \left(\frac{r_2}{r_1}\right) \tan \left(\frac{T}{4\pi G r_2^2 l_2}\right) \quad \ldots\ldots [37]$$

$$\theta_2 \text{ (in deg)} = 132 \log_{10} \left(\frac{r_2}{r_1}\right) \tan \left(\frac{T}{4\pi G r_2^2 l_2}\right) \quad \ldots\ldots [38]$$

CASE 5. CIRCULAR DOUGHNUT SANDWICH USED IN ANGULAR SHEAR, FIG. 15

The metal plates are vulcanized to the rubber. Apply torque T to the plates.

(a) *For Small Deflections*

If deflections are small, $\theta l \backsimeq \phi r$ $\ldots\ldots [39]$

Also, $S = G\theta$ and the torque given to the ring at radius $r = dT$, where $dT = (2\pi r dr)rS$

$$\therefore dT = 2\pi r^2 G\theta dr \quad \ldots\ldots [40]$$

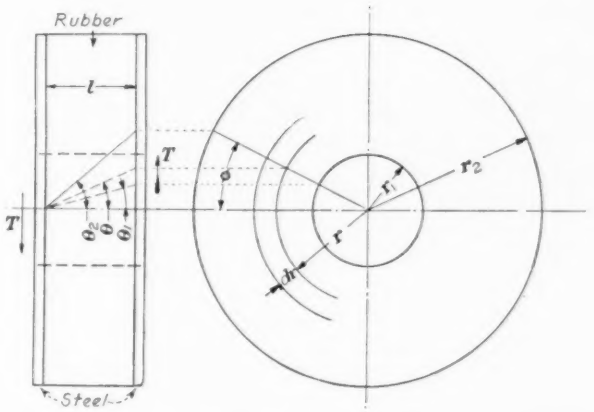

FIG. 15 CIRCULAR DOUGHNUT SANDWICH IN ANGULAR SHEAR

$$\therefore T = 2\pi G \int_{r_1}^{r_2} r^2\theta dr = \frac{2\pi G\phi}{l} \int_{r_1}^{r_2} r^3 dr = \frac{2\pi G\phi}{4l} (r_2^4 - r_1^4)$$

$$= 1.5708 \frac{G\phi}{l} (r_2^4 - r_1^4) \ldots [41]$$

Thus, if ϕ is in radians, $T = 1.5708G\phi(r_2^4 - r_1^4)/l$ $\ldots\ldots [42]$

and, if ϕ is in degrees, $T = 0.0274G\phi(r_2^4 - r_1^4)/l$ $\ldots\ldots [43]$

(b) *For Large Deflections*

In this case $\theta l \neq \phi r$. More correctly, $r\phi/l = \tan \theta$. $S = G\theta$ and $dT = 2\pi r^2 dr S = 2\pi G r^2 \theta dr$.

$$\therefore T = 2\pi G \int_{r_1}^{r_2} r^2\theta dr = 2\pi G \int_{r_1}^{r_2} r^2 \tan^{-1} \frac{r\phi}{l}\, dr \ldots [44]$$

Let $r\phi/l = p$, $\therefore dr = (l/\phi)dp$, and $r^2 = l^2p^2/\phi^2$

$$\therefore T = \frac{2\pi G l^3}{\phi^3} \int_{r=r_1}^{r=r_2} p^2 \tan^{-1} p\, dp$$

$$= \frac{2\pi G l^3}{\phi^3} \left[\frac{p^3}{3} \tan^{-1} p - \frac{p^2}{6} + \frac{1}{6} \log_e (1 + p^2)\right]_{r=r_1}^{r=r_2}$$

$$= \frac{2\pi G l^3}{3\phi^3} \left\{\left(\frac{r_2\phi}{l}\right)^3 \tan^{-1}\left(\frac{r_2\phi}{l}\right) - \left(\frac{r_1\phi}{l}\right)^3 \tan^{-1}\left(\frac{r_1\phi}{l}\right)\right.$$

$$- \tfrac{1}{2}\left[\left(\frac{r_2\phi}{l}\right)^2 - \left(\frac{r_1\phi}{l}\right)^2\right] + \tfrac{1}{2} \log_e \left[1 + \left(\frac{r_2\phi}{l}\right)^2\right] - \tfrac{1}{2} \log_e$$

$$\left.\left[1 + \left(\frac{r_1\phi}{l}\right)^2\right]\right\}$$

$$\therefore T = \frac{2\pi G}{3}\left[r_2^3 \tan^{-1}\left(\frac{r_2\phi}{l}\right) - r_1^3 \tan^{-1}\left(\frac{r_1\phi}{l}\right)\right]$$

$$- \frac{\pi G l}{3\phi} [r_2^2 - r_1^2] + \frac{\pi G l^3}{3\phi^3} \log_e \left[\frac{1 + \left(\frac{r_2\phi}{l}\right)^2}{1 + \left(\frac{r_1\phi}{l}\right)^2}\right] \ldots [45]$$

(c) *First Degree of Approximation*

Let $R = (r_1 + r_2)/2$, $t = r_2 - r_1$, θ = angle at radius R, and S = average stress in rubber. Then $T = 2\pi R^2 tS$ and $S = G\theta$.

$$\therefore T = 2\pi G\theta \{[(r_1 + r_2)^2/4](r_2 - r_1)\}$$

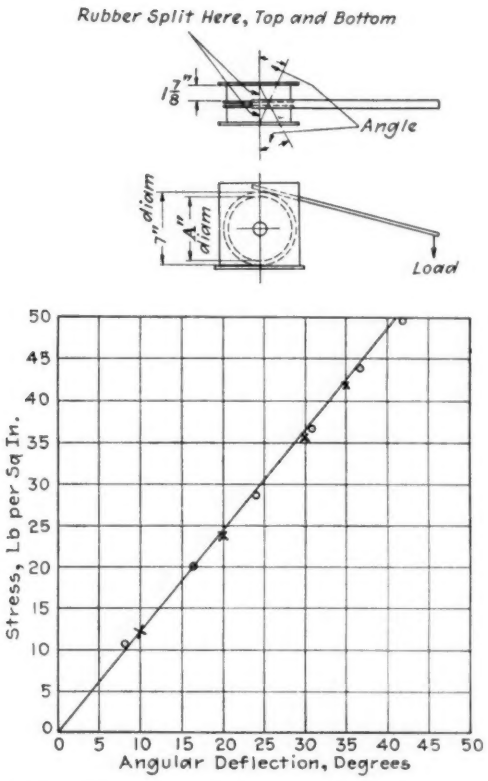

FIG. 17 THEORETICAL LOADING CURVE AND EXPERIMENTAL POINTS

(Rubber: 43 durometer; area (twice cross section) = 25 sq in. for $A = 5\frac{3}{4}$ in. and 45.2 sq in. for $A = 4\frac{1}{2}$ in.
Solid line = theoretical curve for both values of A.
Plotted points are experimental, $A = 4\frac{1}{2}$ in. represented by crosses and $A = 5\frac{3}{4}$ in. represented by circles.)

$$= (\pi G\theta/2)(r_1 + r_2)^2(r_2 - r_1) \quad [46]$$

Also $\tan\theta = d/l$ and $d/R = \phi$, $\therefore \tan\theta = R\phi/l$.
This is definitely applicable where $(r_2 - r_1)$ is small compared with r_1.

In Fig. 16 are shown data for two sizes of rubber doughnut sandwich. The experimental data and the theoretical curves obtained from Equations [43] and [45] are in striking agreement. The remarkably good agreement of experiment with the theoretical Equation [46] (see Fig. 17) makes it appear that this first degree of approximation can be used satisfactorily where $r_2 - r_1$ is small compared with r_1.

CASE 6. DOUGHNUT SANDWICH WITH CONICAL FACES, FIG. 18

Let S = the shear stress in the rubber at radius r
S_1 = the shear stress at the bonded surface = $S\cos\alpha = S\{r_2/[r_2^2 + (l_2/2)^2]^{1/2}\}$
θ = angle of twist of the fiber AB

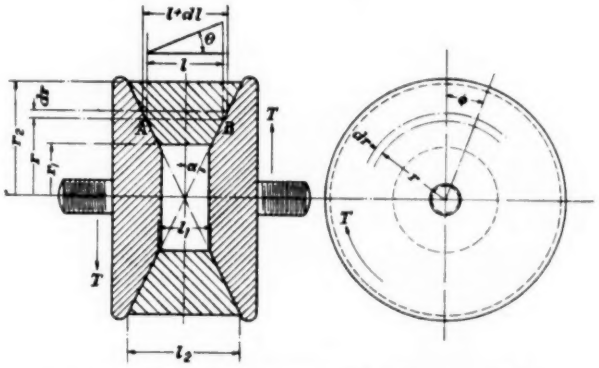

FIG. 18 DOUGHNUT SANDWICH WITH CONICAL FACES

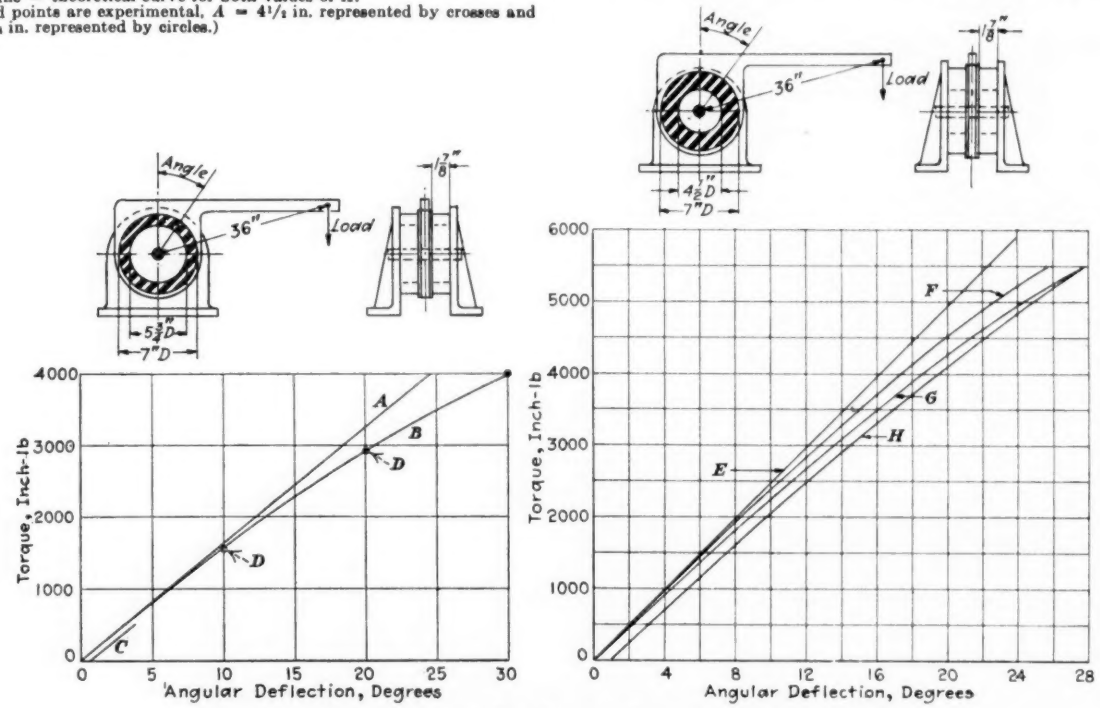

FIG. 16 LOADING CURVES FOR TWO SIZES OF RUBBER DOUGHNUT SANDWICH

(Spring (a). Rubber: area (2 × area of cross section), 25 sq in., 43 durometer.
Curve A, theoretical curve for small deflections.
Curve B, experimental loading curve.
Curve C, experimental unloading curve.
Points D, calculated from theoretical curve for large deflections.)

Spring (b). Rubber: area, 45.16 sq in., 43 durometer.
Curve E, theoretical curve for small deflections, $T = 247.2\phi$.
Curve F, theoretical curve for large deflections.
Curve G, experimental loading.
Curve H, experimental unloading.)

$S = G\theta$, and $\tan\theta = r\phi/l$

But $l/r = l_2/r_2 = l_1/r_1 = \text{const.}$
Therefore, for a definite angle ϕ, both θ and S are constant.
Now $dT = 2\pi r^2 dr S$

$$\therefore\ T = 2\pi S \int_{r_1}^{r_2} r^2 dr = \frac{2\pi S}{3}(r_2^3 - r_1^3) \quad [47]$$

and $S = G\theta = G\tan^{-1}(r_2\phi/l_2)$

$$\therefore\ T = (2/3)\pi G(r_2^3 - r_1^3)\tan^{-1}(r_2\phi/l_2) \quad [48]$$

or
$$\phi = (l_2/r_2)\tan\{3T/[2\pi G(r_2^3 - r_1^3)]\} \quad [49]$$

Notice that Equation [48] is almost the same as the first term of Equation [45].

It is hoped that the preceding calculations and experimental data will be helpful to those who deal with rubber mountings. It is realized, of course, that although in every case plain shear has been assumed for the sake of simplicity, compound stresses are ordinarily encountered. The effect of these stresses on the shear load-deflection data is seen to be small, and thus there is justification for using the simpler calculations.

Acknowledgment is due to F. L. Yerzley of E. I. du Pont de Nemours and Company for helpful criticism after preparation of the paper.

Solution of Rectangular Clamped Plate With Lateral Load by Generalized Energy Method[1]

By GERALD PICKETT,[2] MANHATTAN, KAN.

The author gives formulas by which the energy method may be readily applied for obtaining the moments and deflections for any lateral load on a clamped rectangular plate. He not only gives mathematical computations illustrating the application of the formulas, but also discusses the accuracy of the method compared to others, and points out its limitations.

THE problem of a thin rectangular plate bent with lateral load and fixed at its edges so that neither deflection nor inclination occurs at the edges, is a problem of frequent discussion in recent technical literature. All solutions are in the form of an infinite series. The coefficients of the terms in the series cannot be definitely determined as is the case in Fourier analysis. Approximate solutions using the first few terms in the series involve the solution of as many linear equations as terms taken. Although all methods of solution have these characteristics in common, they differ in details.

The energy method was developed by Timoshenko (1)[3] and Ritz (2). Timoshenko used it for the solution of the simply supported plate, while Ritz used it for the clamped plate. In his solution, Ritz used the normal functions of a doubly clamped bar. These functions are complicated, and the labor involved in obtaining numerical results is almost prohibitive. Shortly after Ritz's death, Knott (3) and Mesnager (4) attempted to obtain numerical values from his method but their results did not agree, as Mesnager's work was incorrect because he did not use the proper functions.

Because the energy method was so laborious, and results from it did not always agree, it lost favor as soon as the methods of Boobnov (5) and Hencky (6) became known.

Generalized Energy Method

In order to obtain correct results with the energy method, it is essential that the proper functions be used. So far as is known, the only correct functions for the deflection of the rectangular clamped plate are those used by Ritz, and the function

$$w = \frac{P}{Dab^3}(x^2 - a^2)^2(y^2 - b^2)^2 \sum_0^\infty{}_m \sum_0^\infty{}_n \alpha_{mn}\left(\frac{x}{a}\right)^m\left(\frac{y}{b}\right)^n \quad \ldots [1]$$

where the plate has dimensions shown in Fig. 1; w is the deflection; P is the total lateral load; D is the flexural rigidity assumed constant; and m and n, as well as r, s, g, and h subsequently used, are integers. In the case of symmetrical loading, only even integers will occur.

The boundary requirements $w = 0$, $\partial w/\partial n = 0$ are satisfied by each term of the series of Equation [1]. The strain energy of bending is given by the integral (7)

$$\int\int \frac{D}{2}\left\{\left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2}\right)^2 - 2(1-\nu)\left[\frac{\partial^2 w}{\partial x^2}\frac{\partial^2 w}{\partial y^2} - \left(\frac{\partial^2 w}{\partial x dy}\right)^2\right]\right\} dx\,dy \quad \ldots [2]$$

It may be shown by the calculus of variations that the integral of the expression in the brackets, over an area from which there is no flow of energy, vanishes. Since there can be no flow of energy past the boundary of a clamped plate, the expression for the total energy U becomes

$$U = \int\int\left[\frac{D}{2}\left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2}\right)^2 - qw\right] dxdy \quad \ldots [3]$$

where q is the intensity of lateral load.

It may be shown also by the calculus of variations that making the total energy a minimum is equivalent to satisfying the differential equations of equilibrium.

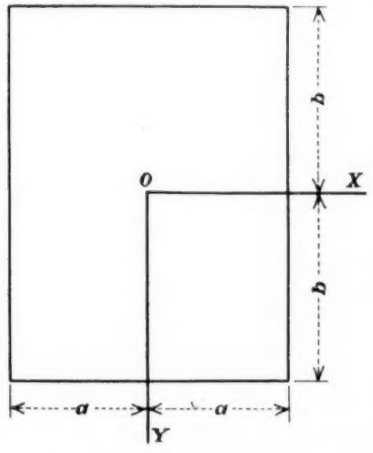

FIG. 1

When Equation [1] is substituted into Equation [3] and the integral minimized by setting

$$\frac{\partial U}{\partial \alpha_{mn}} = 0 \quad \ldots [4]$$

a set of linear equations is obtained from which the matrix of α's may be determined to any desired accuracy. There will be an equation associated with each α; for example, the mn equation associated with α_{mn} is found from Equation [4] and may be written as

$$C_{mn00}\,\alpha_{00} + C_{mn10}\,\alpha_{10} + C_{mn01}\,\alpha_{01} + C_{mn20}\,\alpha_{20} + \ldots\ldots + C_{mnrs}\alpha_{rs} + \ldots\ldots = q_{mn} \quad \ldots [5]$$

Presented at the Annual Meeting, Philadelphia, Pa., December 4–8, 1939, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

NOTE: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

where C_{mnrs} is a coefficient of α_{rs} in the mn equation and is a function of the integers m, n, r, and s, and the ratio of a to b. Also q_{mn} is a function of m, n, and the loading q. The calculations show that C_{mnrs} may be written as

$$C_{mnrs} = R_{mr}T_{ns} + 2S_{mr}S_{ns}(a^2/b^2) + T_{mr}R_{ns}(a^4/b^4)$$

where

$$R_{gh} = R_{hg} = \frac{384[2g^2h^2 + 2gh(g+h) + g^2 + h^2 - 8gh - 4(g+h) + 3]}{(g+h+5)(g+h+3)(g+h+1)(g+h-1)(g+h-3)}$$

$$S_{gh} = S_{hg} = \frac{128\,[g^2 + h^2 - 4gh - 3(g+h) + 2]}{(g+h+7)(g+h+5)(g+h+3)(g+h+1)(g+h-1)}$$

$$T_{gh} = T_{hg} = \frac{768}{(g+h+9)(g+h+7)(g+h+5)(g+h+3)(g+h+1)}$$

Before the derivation of the foregoing equations, the determination of any coefficient of α represented considerable work and consequently only those necessary for the first few equations had been evaluated. Since the coefficients of the α's are obtained from the strain-energy portion of Equation [3] they are independent of the loading. The effect of loading distribution shows itself in the value of q_{mn} which is obtained from the remaining portion of the integral. In the case of concentrated loads, the q's are obtained without integration. For example, $q_{00} = 1$, and all other q's are zero for a concentrated load at the center. For a uniform load over the entire plate

$$q_{mn} = \frac{64}{(m+5)(m+3)(m+1)(n+5)(n+3)(n+1)}$$

The q's for other distributions are readily obtained as soon as q as a function of x and y is known. As an additional example, suppose there is a uniform load over the middle fourth of the plate, that is, from $-a/2$ to $+a/2$, and $-b/2$ to $+b/2$. We then have

$$q_{mn} = \frac{(9m^2 + 84m + 203)(9n^2 + 84n + 203)}{2^{m+n+8}(m+5)(m+3)(m+1)(n+5)(n+3)(n+1)}$$

It is recommended that the C's be evaluated from a prepared table, as shown by Table 1.

From Table 1 it may be seen, for example, that

$$C_{2044} = C_{4420} = C_{4024} = C_{2440} = \left(\frac{6784}{1155} \times \frac{256}{15015}\right) - \left(2 \times \frac{512}{6435} \times \frac{256}{3465}\frac{a^2}{b^2}\right) + \left(\frac{128}{105} \times \frac{256}{45045}\frac{a^4}{b^4}\right)$$

Using only one parameter α_{00}, for a square plate with uniform load we have

$$C_{0000}\,\alpha_{00} = q_{00}$$

where

$$C_{0000} = \left(\frac{128}{5} \times \frac{256}{315}\right) + \left(2 \times \frac{256}{105} \times \frac{256}{105}\right) + \left(\frac{256}{315} \times \frac{128}{5}\right)$$

and

$$q_{00} = \frac{64}{225}$$

10. The number of parameters will be the same as the number of linear equations in general, but for a square plate, only six equations are necessary for nine parameters: ten equations for sixteen parameters, etc.

from which $\alpha_{00} = 0.0053168$. Using only this one parameter, it is found that it gives a deflection at the center 5.04 per cent too large; a deflection at $(x = a/2, y = 0)$ 1.4 per cent too small; and a moment at the middle of a clamped edge 17.0 per cent too small.

Computed values of deflections and moments of a square plate under three different types of loads are given in Table 2. Examination of this table shows that four parameters are sufficient for

13. Calculations were carried to eight significant figures but fewer are shown in the table to conserve space.

an accuracy of three significant figures for uniform load. The values shown using four or more parameters agree with calculations made by other methods.[4] It was pointed out in the author's dissertation[1] that nine parameters were necessary for such accuracy when the ratio of length to breadth was 1.75.

Very good accuracy is also indicated for four parameters when the load is distributed over the central fourth of the plate. In the case of a concentrated load at the center, the values for moments are not as accurate. Timoshenko (9) gives a value of the moment at the middle of the clamped edge of $-0.1257P$.

In addition to the method described in this paper, the author has solved the uniformly loaded clamped square plate by all of the following methods: Energy method using functions proposed by Ritz (2), Hencky method (6), elastic-web method of Marcus (8) power-series integration,[1] and superposition method of Timoshenko (9). Also he has used some of these methods for concentrated loads and for plates not square.

As to which method is the better depends upon the type of loading, the ratio of length to breadth, what is wanted; that is, deflection, moment or shear, and the degree of accuracy desired. The method of Timoshenko is found to be the best for a concentrated load at the center. His method gives very good results in this case because a very rapidly converging series solution is known for the simply supported case.

The advantages of the energy method using the series Equation [1] were discussed in the author's dissertation.[1]

Solving Simulataneous Linear Equations

Since all methods involve the solution of a set of linear equations, and since it may be necessary to solve ten or more such equations to obtain the desired accuracy, the method found to be most satisfactory to the author will be explained.

One does not know at the beginning, how many parameters will be necessary. It will be found most economical of time to start with one or two parameters then continue to take more, as shown in Table 2, until the desired accuracy is indicated.

The author has found that the method illustrated in Table 3, where practically all of the computations are shown for the solution of six equations and six unknowns for three different loading conditions, gives accurate results with a minimum of computations. Every operation is outlined in advance so that two computers working simultaneously would have identical computations unless a mistake had been made. With this method, mistakes are easily detected; therefore, the solutions may be as accurate as the computing machine.

Conclusions

With the general formulas given in this paper available, the energy method may be readily applied for obtaining the moments and deflections for any lateral load on a clamped rectangular plate. It is believed that for fair accuracy, with all except a few types of loading, it has advantages over other known methods. It does not give as good results for concentrated loads as for distributed loads, and is inferior to Timoshenko's method for a concentrated load at the middle.

[4] The value given by Hencky and others for the moment at $(a, 0)$ is $-0.0513P$, and for the deflection coefficient at (0, 0) is 0.0138 which when reduced to the proper notation becomes 0.005055.

Chain Links Under Cross Forces

By JOS. B. REYNOLDS,[1] BETHLEHEM, PA.

This paper develops theory for stresses and deflections of links with circular neutral axes when freely supported at the ends of one diameter and loaded with two equal loads, perpendicular to the plane of the neutral axis, at the ends of the diameter perpendicular to the first. It also develops theory for deflections of oblong links whose neutral axes consist of semicircles connected by straight sides when supported at the middle points of the end arcs and loaded with equal loads perpendicular to the plane of the neutral axis at the midpoints of the sides. The theory is checked by experimental tests.

IT IS WELL known that a chain will fail under a much smaller load when the links are subjected to a cross pull than when subjected to a direct pull. Cross pulls may arise from many causes. Chains may be pulled around a corner or pole, wound on a cylinder or capstan, or kinked or knotted so as to produce forces across the plane of the neutral axis of a link.

Because of the uncertainty of the occurrence of such situations many engineers avoid as far as feasible the use of chains, replacing them by cables. But cables also have their dangerous characteristics. It is common practice in making anchor chains to put a stud across the middle of an oblong link in order to prevent tangling and kinking of the chain. While this expedient prevents certain dangerous situations it does not eliminate all. For certain purposes the chain, if not the only, is certainly the best device.

It is the purpose of this paper to develop theory for stresses and deflections when links of different shapes are subjected to certain symmetrical loading perpendicular to the plane of the neutral axis of the link and to compare the results of theory with those obtained from tests in an engineering laboratory.[2]

Outline of Tests

Tests were performed on three specimens. No. 1 was a circular link of forged steel $10^{15}/_{16}$ in. OD, accurately made of 2-in. round stock. It will be called the round circular link. This link was first tested for stresses and vertical and angular deflections, then annealed and again tested for deflections.

No. 2 was a circular link of forged steel $10^{15}/_{16}$ in. OD, accurately made of 2-in. square stock. It will be called the square circular link. This link was annealed and tested for vertical and angular deflections.

No. 3 was an oblong link of cast steel assumed to be made up of two semicircular ends connected by equal straight sides. It will be called the oblong link. It was 13.61 in. long and 8.16 in. wide, made of 2.26-in. round stock. It was tested for vertical and angular deflections.

A link whose principal mutually perpendicular axes are AC and BD (Fig. 1) was supported on rollers or spherical bearing blocks at A and C, and two equal vertically downward forces were applied at B and D by a spherical loading block centered in an Olsen testing machine over the center of the link. The setup for the round circular link is shown in Fig. 2.

Stresses at the upper surface of this link were measured by means of an extensometer. In the case of each link tested the vertical deflection was measured under the loaded points and over the supported points by means of Ames gages reading to 0.0001 in. The angular deflection or turning of the stock over the points of support was measured by determining the angular rotation of arms welded to the link in the line of the axis AC over the supports. This rotation measured by Ames gage readings at points at a measured distance apart on the arms was checked by deducing from it a deflection of the neutral axis which was then compared with the deflection determined by direct readings on the gages at A, B, C, and D.

The method of performing these separate tests for stresses, vertical deflection, and angular rotation will now be described and the results compared with theoretical values.

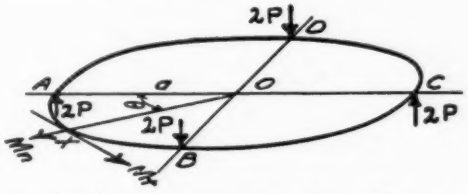

Fig. 1 Circular Neutral Axis of Links Nos. 1 and 2

Notation

- A = point on neutral axis directly over support
- AB = one quadrant of neutral axis
- A_s = area of cross section of stock
- a = radius of neutral axis
- E = Young's modulus
- G = modulus of shear
- I_n = moment of inertia of A_s with respect to the normal to the neutral axis
- I_t = moment of inertia of A_s with respect to the tangent to the neutral axis
- k = angular rotation of stock at supports
- L = total load
- l = length of one half of straight side for oblong links with semicircular ends
- M_o = bending moment at A
- M_n = moment about normal to neutral axis
- M_t = moment about tangent to neutral axis
- O = center of circular neutral axis
- P = $L/4$
- r = radius of circular stock
- S = stress
- X = any point on the arc AB
- z = vertical deflection of point X
- z' = value of z at B
- θ = central angle AOX

Tests for Stresses

On the upper side of the round circular link beginning at the points A and C directly over the supports six small shallow holes

[1] Professor of Mathematics and Theoretical Mechanics, Lehigh University.

[2] The specimens required for these tests were generously provided by the Baldt Anchor, Chain, and Forge Corporation of Chester, Pa. The tests were made at the Fritz Engineering Laboratory, Lehigh University, under the direction of Professor Inge Lyse whose suggestions and criticisms have been very helpful to the author.

Presented at the National Meeting of the Applied Mechanics Division of The American Society of Mechanical Engineers, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1940, for publication at a later date.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of authors, and not of the Society

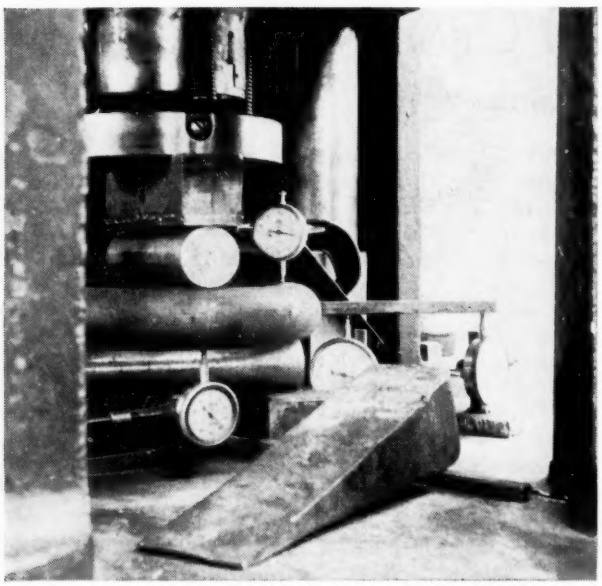

FIG. 2 LOADING ARRANGEMENT OF CIRCULAR LINK

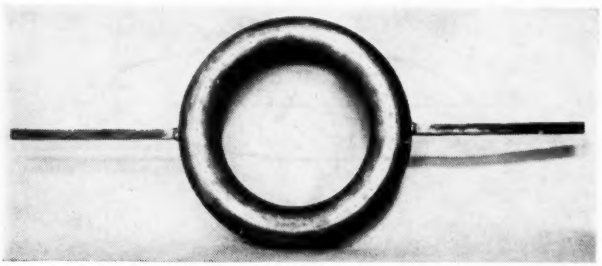

FIG. 3 ROUND CIRCULAR LINK WITH STRAIN-GAGE HOLES AND ANGULAR-ROTATION ARMS

were sunk at distances of about one inch apart in each direction along the circular arc directly above the neutral axis.[3] See Fig. 3. Beginning at the end hole of each series of holes, extensometer measurements were made from each hole to the second following one and the measured strain in each distance was taken as the strain at the midpoint of the arc subtended by the measurement. First readings were taken under a load of 1000 lb.

Conditions for the four quadrants are obviously symmetrical. The results obtained on the four arcs averaged for each of five angular distances from the supports are given in the third column of Table 1. These values represent increases of stresses over the initial stresses. In the fourth column are given corresponding theoretical increases in stresses at these points computed from $SI_n = rM_n$ in which

$$M_n = Pa\,(\sin\theta - \cos\theta) \quad \ldots\ldots\ldots\ldots\ldots [1]$$

The results are depicted graphically in Fig. 4. Because of the limitations of the extensometer, observations are incomplete for $\theta = 0$. Indications are that the elastic limit is reached over the supports under a load of from 20,000 to 30,000 lb. From deflections it was found to occur at about 25,000 lb.[4]

In Fig. 5 are plotted the bending moment along the arc AB as computed from Equation [1] and, also, the moment due to twist given by

$$M_t = Pa\,(\sin\theta + \cos\theta - 1) \quad \ldots\ldots\ldots\ldots [2]$$

[3] The neutral-axis radius is taken as 4.47 in. No consideration is here given to the slight shifting of the neutral axis away from the geometric axis due to curvature. After the stress test this link was annealed to remove initial and set stresses and tested again. Its deflection behavior in the second test nearly duplicated that of the first which is not given for the sake of clarity.

[a] Stress values represent increases in stress over that at the initial load of 1000 lb.

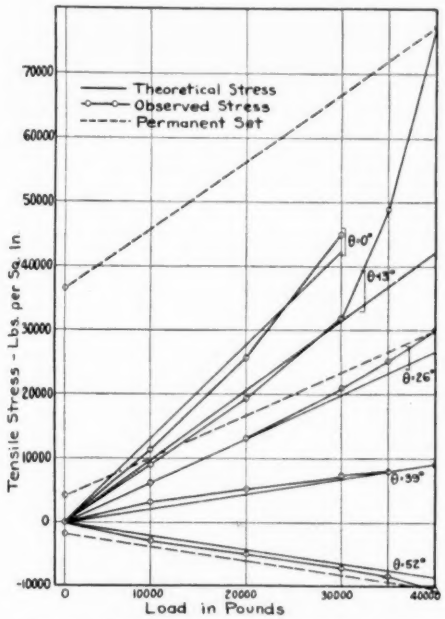

FIG. 4 STRESSES IN ROUND CIRCULAR LINK

[4] On a straight pull the elastic limit for this link was found to be about 17,000 lb, a ratio of 1 to 1.47. The theoretical ratio is about 14 to 3 or 1 to 1.49.

No observations were made to determine directly values of M_t but they are indirectly involved in the deflections upon which careful observations were made. The total stress at any point depends upon M_n and M_t combined with a small stress due to vertical shear.

Tests for Vertical Deflections

The vertical deflection z' of the neutral axis of the links under the applied loads at B and D, Fig. 1, was measured in two ways which may be described by reference to Fig. 6 which shows the setup for the square circular link. First, the gross deflection was measured by gages set up under the specimen at points directly under the loads. From this was subtracted the amount of settling of the specimen determined by gages set up at points directly over the supports. The average values thus found for the two points under the loads were taken as the measured deflection determined by this method. It is called deflection by direct measurement.

Second, from the readings of the two gages farthest right in the figure (one only partially visible), the distance between them, and the distance from the inner gage to the neutral axis, the point of rotation of the arm and downward motion of the neutral axis were determined by simple geometric considerations. The average deflection thus determined by the two arms is called deflection by indirect measurement or rotation of arms.

First readings were taken under an initial load of 1000 lb. In the first run readings were taken at 1000, 5000, 10,000, 15,000, and 20,000 lb. The load was then eased off to 1000 lb and the

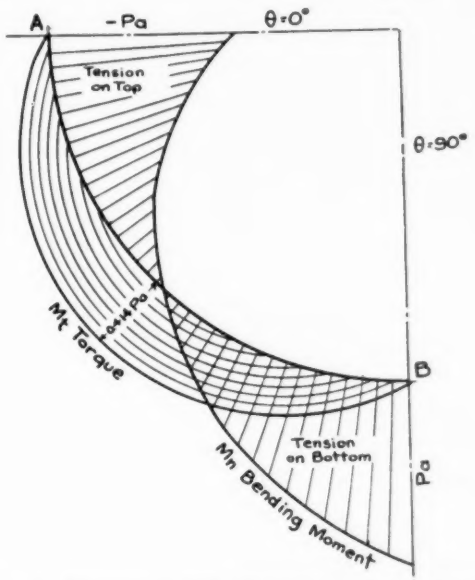

Fig. 5 Moments in One Quadrant of Circular Link

second run made as before to a maximum of 25,000 lb. The maximum was then increased for succeeding runs by steps of 5000 lb until the elastic limit was reached. In the second run, only, in the case of each link the load was eased off from the maximum by steps of 5000 lb until the initial load was again reached. The values of deflections thus obtained are averages of from two to sixteen readings.

The theoretical deflection for the round circular link, as given by Equation [23] in the Appendix with $\theta = \pi/2$, is

$$z' = \frac{Pa^3}{GI_t}(\pi - 3) + \frac{Pa^3}{2EI_n}(\pi - 2) + \frac{P\pi a}{2A_eG}$$

which for $E = 3 \times 10^7$ and $2.6G = E$, a ratio used by Timoshenko,[5] gives

$$z' = 7.68 \times 10^{-7}L \quad [3]$$

Similarly, for the square circular link

$$z' = \frac{42.6Pa^3}{A_e^4G} I_t(\pi - 3) + \frac{Pa^3}{2EI_n}(\pi - 2) + \frac{P\pi a}{2A_eG} = 4.77 \times 10^{-7} L \quad [4]$$

and for the oblong link

$$z' = \frac{Pa^3}{GI_t}(\pi - 3) + \frac{Pa^3}{2EI_n}(\pi - 2) + \frac{Pl(l^2 + 3al + 3a^2)}{3EI_n} + \frac{P}{2A_eG}(\pi a + 2l) = 4.89 \times 10^{-7}L \quad [5][6]$$

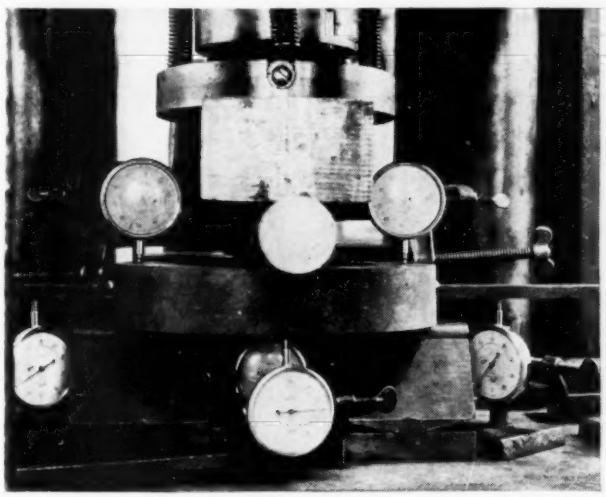

Fig. 6 Loading Arrangement for Square Circular Link

In Table 2 are set forth the observed and theoretical values of the deflection z' at points directly under the loads. These results are exhibited graphically in Figs. 7 and 8.

Tests for Angular Rotation Over Supports

As the link deflects under load the stock turns about the tangent to the neutral axis at points over the supports. The theory gives for the amount k of this turning in radians for the round circular link

$$k = \frac{Pa^2}{4}(\pi - 2)\left(\frac{1}{GI_t} + \frac{1}{EI_n}\right) = 1.39 \times 10^{-7}L \quad [6]$$

for the square circular link

$$k = \frac{Pa^2}{4}(\pi - 2)\left(\frac{42.6I_t}{A_e^4G} + \frac{1}{EI_n}\right) = 0.827 \times 10^{-7}L \quad [7]$$

and for the oblong link

$$k = \frac{Pa^2}{4}(\pi - 2)\left(\frac{1}{GI_t} + \frac{1}{EI_n}\right) + \frac{Pl(2a + l)}{2EI_n} = 1.123 \times 10^{-7}L \quad [8]$$

[5] "Strength of Materials," by S. Timoshenko, part 1, D. Van Nostrand Company, New York, N. Y., 1930, page 59, art. 16.

[6] The link used for this test only approximately meets the slope required by the theory. The values $l = 3$ and $a = 2.68$ in. were judged best from a plain section containing a neutral axis of the link.

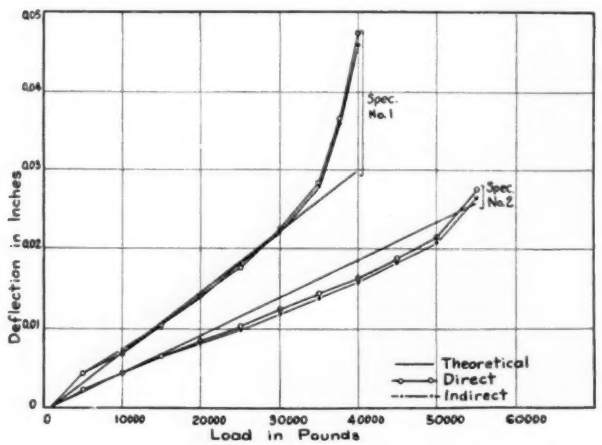

FIG. 7 DEFLECTION OF CIRCULAR LINKS UNDER LOADING POINTS

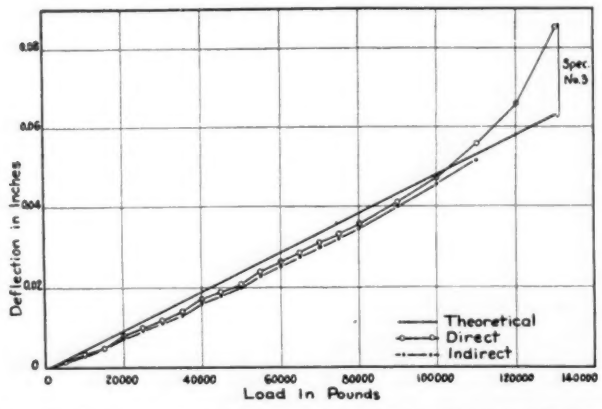

FIG. 8 DEFLECTION OF OBLONG LINK UNDER LOADING POINTS

Values of k were found from observation by dividing the change in elevation of two points on the arms welded to the links, determined by gage readings, by the distance between the points.[7] Each value thus determined is the average of from two to sixteen readings depending upon how often the particular load in question was applied. The results are closely checked by the fact that deflections determined from the values of k, as seen by Figs. 7 and 8 agree closely with those determined by direct measurement.

The observed and theoretical values of k for the different links are set forth in Table 3. This table gives the increases in rota-

[a] Increase in rotation after initial load of 1000 lb.

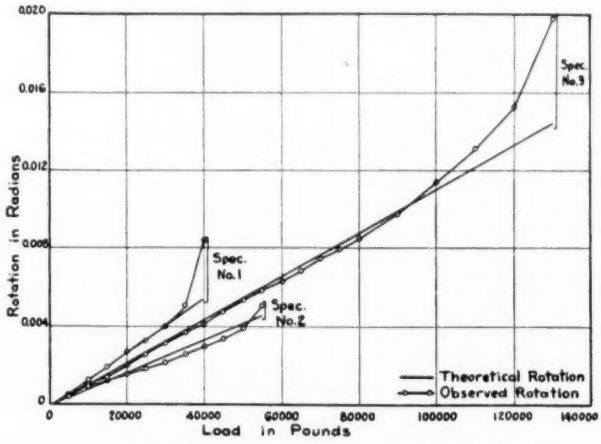

FIG. 9 ROTATION OF LINKS OVER SUPPORTS

[7] This method takes no account of change in slope of the cross section under load. The change must be very small for the loads applied.

tion after the application of the initial load of 1000 lb. These results are depicted graphically in Fig. 9.

Appendix

Theory of Deflection of Circular Ring

The deflection under consideration is caused by a vertical load $4P$, applied in two equal parts at the ends of a diameter of a horizontal circular ring, of geometric axis radius a and circular cross-sectional area A_c, supported by vertical forces at the ends of a diameter perpendicular to the loaded diameter. Let any point X on the neutral axis be located by the central angle θ measured from a support. See Fig. 10. Let M_t and M_n be the moments exerted by the section perpendicular to the neutral axis to the right of X on that to the left about the tangent and normal to the neutral axis, respectively, with positive senses as indicated by arrowheads in the figure.

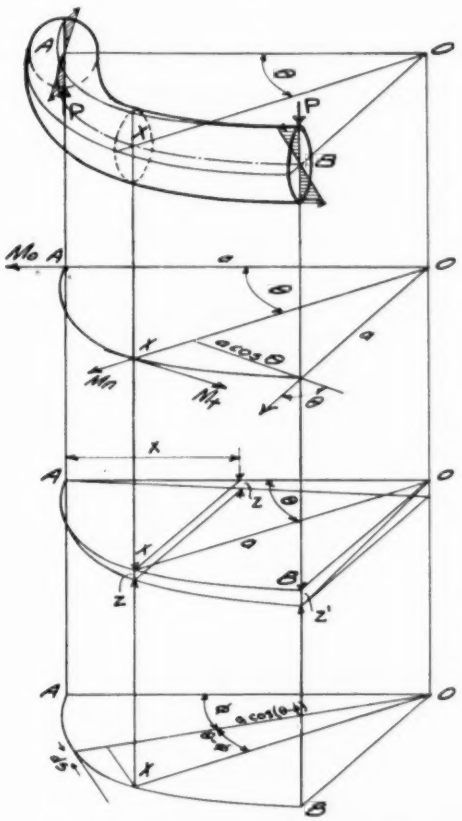

Fig. 10 One Quadrant of Circular Ring

Let z be the vertically downward deflection of the point X. Then four effects contribute to z: The twisting about the tangent; the twisting about the normal or bending; the detrusion due to vertical shear; and a free rotation about the point A. Let the component of z yielded by the twisting about the tangent be represented by z_t, that about the normal by z_n, that due to vertical shear by z_s, and let k be the angle of free rotation. Then

$$z = z_t + z_n + z_s + ka\,(1 - \cos\theta) \quad \ldots\ldots [9]$$

since x in the figure equals $a\,(1 - \cos\theta)$.

Let the stock at a point determined by the central angle ϕ be twisted through an angle dw_t in a length ds of the arc $AX = s$ of the neutral axis. Then the deflection, z_t, at X due to this twist is such that

$$dz_t = -a[1 - \cos(\theta - \phi)]dw_t \quad \ldots\ldots [10]$$

where

$$dw_t = \frac{M_t ds}{GI_t} \quad \ldots\ldots [11]$$

with G being the modulus of shear and I_t the polar moment of inertia of the cross section of the stock with respect to its center. Hence

$$z_t = \frac{-a}{GI_t}\int [1 - \cos(\theta - \phi)]\, M_t ds \quad \ldots\ldots [12]$$

Now

$$M_t = M_0 \cos\phi - Pa\,(1 - \sin\phi) = Pa\,(\sin\phi + \cos\phi - 1) \quad \ldots [13]$$

since by taking moments about A we get $M_0 = Pa$. Replacing ds in Equation [12] by $ad\phi$ and substituting for M_t its value from Equation [13] we have

$$z_t = -\frac{Pa^3}{GI_t}\int_0^\theta [1 - \cos(\theta - \phi)][\sin\phi + \cos\phi - 1]\, d\phi \quad \ldots [14]$$

which evaluates to

$$z_t = \frac{Pa^3}{GI_t}\left[\theta + \cos\theta - 1.5\sin\theta - 1 + \frac{\theta}{2}(\sin\theta + \cos\theta)\right] \quad \ldots [15]$$

To determine the effect due to bending we have

$$dz_n = -a\sin(\theta - \phi)\, dw_n,\ dw_n = \frac{M_n ds}{EI_n} \quad \ldots\ldots [16]$$

in which E is Young's modulus and I_n the moment of inertia of a cross section of the stock with respect to the normal to the neutral axis. Now

$$M_n = M_0 \sin\phi - Pa\cos\phi = Pa\,(\sin\phi - \cos\phi) \quad \ldots [17]$$

and therefore

$$z_n = \frac{Pa^3}{EI_n}\int_0^\theta (\cos\phi - \sin\phi)\sin(\theta - \phi)\, d\phi$$

$$= \frac{Pa^3}{2EI_n}[\theta(\sin\theta + \cos\theta) - \sin\theta] \quad \ldots\ldots [18]$$

Due to vertical shear we have the detrusion

$$z_s = \frac{Pa\theta}{A_c G} \quad \ldots\ldots [19]$$

For the total deflection we have by Equations [15], [19], and [9]

$$z = \frac{Pa^3}{GI_t}\left[\theta + \cos\theta - 1.5\sin\theta - 1 + \frac{\theta}{2}(\sin\theta + \cos\theta)\right] + \frac{Pa\theta}{A_c G} + \frac{Pa^3}{2EI_n}[\theta(\sin\theta + \cos\theta) - \sin\theta] + ka\,(1 - \cos\theta) \quad \ldots [20]$$

By considerations of symmetry we see that k must have such a value that where $\theta = \pi/2$ at B, $\frac{dz}{ds}$ the slope of the neutral axis

shall be the same as at A where $\theta = 0$. From Equation [20]

$$\frac{dz}{ds} = \frac{dz}{ad\theta} = \frac{Pa^2}{GI_t}\left[1 - \frac{\sin\theta}{2} - \cos\theta + \frac{\theta}{2}(\cos\theta - \sin\theta)\right] + \frac{P}{A_cG} + \frac{Pa^2}{2EI_n}[\theta(\cos\theta - \sin\theta) + \sin\theta] + k\sin\theta \ldots [21]$$

Setting Equation [21] equal to $\frac{P}{A_cG}$ for $\theta = \pi/2$, gives

$$k = \frac{Pa^2}{4}(\pi - 2)\left(\frac{1}{GI_t} + \frac{1}{EI_n}\right) \ldots\ldots\ldots [22]$$

which by Equation [20] gives for the total deflection

$$z = \frac{Pa^3}{GI_t}\left[\theta - 1.5\sin\theta + \frac{\theta}{2}(\sin\theta + \cos\theta) - \frac{6-\pi}{4} \times (1 - \cos\theta)\right] + \frac{Pa\theta}{A_cG} + \frac{Pa^3}{2EI_n}\left[\theta(\sin\theta + \cos\theta) - \sin\theta + \frac{(\pi-2)}{2}(1 - \cos\theta)\right] \ldots [23][8]$$

If the cross section of the ring is a square instead of a circle we must replace $\frac{1}{I_t}$ by $\frac{42.6I_t}{A_c^4}$ in Equations [22] and [23].[9] The values z' of z for $\theta = \pi/2$ are obtained from Equation [23] before and after this substitution. Similarly the numerical values for k are found.

Theory for Oblong Link

The neutral axis of the oblong link here considered mathematically consists of two semicircles of radius a connected by straight sides each of length $2l$. The supports are assumed to be at the middle of the semicircular ends and the loads applied at the midpoints of the straight sides though they might be taken vice versa with the same results. Fig. 11 shows one of the symmetrical quarters of the link. Since the force P at B is equivalent to a force P at C combined with a moment of magnitude P, the physical state of the quadrant of the semicircular end is the same as for the circular ring except that the slope at B is different.

Now the moment M_0 at A is, as before, equal to Pa and the moment M_1 at B is equal to $P(a + l)$. Let y be the deflection below C of any point on the straight side at distance x from C; then

$$EI_n\frac{d^2y}{dx^2} = P(l - x) - M_1 = -P(x + a) \ldots\ldots [24]$$

Integration of this equation with the conditions that the slope is P/A_cG at B and the deflection zero at C gives

$$EI_n\frac{dy}{dx} = \frac{P}{2}[(l + a)^2 - (x + a)^2] + \frac{PEI_n}{A_cG} \ldots\ldots [25]$$

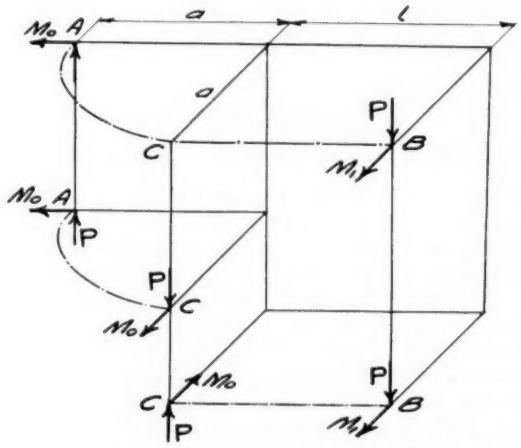

Fig. 11 Neutral Axis of Oblong Ring

and

$$y = \frac{P}{6EI_n}[3(l + a)^2x - (x + a)^3 + a^3] + \frac{Px}{A_cG} \ldots [26]$$

From these we obtain for the slope at C and the deflection at B respectively

$$\frac{dy'}{dx} = \frac{Pl(2a + l)}{2EI_n} + \frac{P}{A_cG} \ldots\ldots [27]$$

and

$$y' = \frac{Pl^2(2l + 3a)}{6EI_n} + \frac{Pl}{A_cG} \ldots\ldots [28]$$

Setting Equation [21], for $\theta = \pi/2$, equal to Equation [27] we find for k, for a circular cross section, the value

$$k = \frac{Pa^2}{4}(\pi - 2)\left(\frac{1}{GI_t} + \frac{1}{EI_n}\right) + \frac{Pl(2a + l)}{2EI_n} \ldots [29]$$

and adding y' from Equation [28] to z from [21] integrated with k from Equation [29] and evaluated for $\theta = \pi/2$, we get for the deflection at B

$$z' = \frac{Pa^3}{GI_t}(\pi - 3) + \frac{Pa^3}{2EI_n}(\pi - 2) + \frac{Pl(l^2 + 3al + 3a^2)}{3EI_n} + \frac{P}{2A_cG}(\pi a + 2l) \ldots [30]$$

for the link of circular cross section.

The deflection at any point on CB at distance x ($x < l$) from C will be given by

$$z = z_c + y \ldots\ldots [31]$$

where z_c is the value of z from Equation [23] for $\theta = \pi/2$ and y is taken from Equation [26].

[8] Since the curve of deflection must be symmetrical with respect to the point where $\theta = \pi/4$ we may apply the following check. Let z_1 be the value of z for $\theta = \pi/4$ and z_2 its value for $\theta = (\pi/2) - \theta$ then we must have $z_1 - z = z_2 - z_1$. This check will be found to be satisfied by Equation [23].

Vibration of Locomotive Driving Wheels Caused by Unbalance

By O. J. HORGER[1] and C. W. NELSON,[2] CANTON, OHIO

Results of road service tests on steam locomotives are presented to show the influence of unbalance in driving wheels in causing vibrations of the wheel on the rail. These results are accompanied by a correlated theoretical study of conditions under which these vibrations occur. A method is given for eliminating such vibrations based on test results. The effect of unbalance and weight of reciprocating parts is also discussed relative to the track and locomotive.

Introduction

IT HAS been known for some time that main driver wheels of steam locomotives intermittently lifted vertically off the rail in road service under certain conditions of speed and counterbalance. When the speed of the locomotive was such that the inertia force of the overbalance, or what was usually underbalance in the main driver wheel, exceeded the load on the wheel, then lifting of the wheel took place. A frequent result of this action was rail damage commonly termed kinks which were located on the head of the rail at intervals equal to the circumference of the driver wheel. It was therefore a relatively simple matter to determine from the driver-wheel diameter of various locomotives which class of locomotive was doing this damage. Kinks which have been found in rail within the last year on some railroads (1, 2)[3] however, have had a spacing along the rail head which is considerably less than the circumference of any driver wheel and any other locomotive or car wheel in operation. In fact the distance between kinks was found to show considerable variations in spacing in any one stretch of damaged track. Theoretical considerations indicated that this damage could be developed by vibrations of the driver wheels at high speeds although the inertia force at such speeds was considered insufficient to cause lifting. Such high speeds are sometimes attained by trains, and high rotative wheel speeds may occur in fast train service due to occasional slipping of the driver wheels produced by grease on the rail at crossings, frosted and wet rail, and so on. Modern high-speed locomotives require judicious handling and alertness on the part of the operating engineer in order to avert or control such slipping tendencies.

As a means of investigating this problem high-speed moving pictures were taken to determine the action between the driver wheel and rail with various steam locomotives[4] in road service at high rotative wheel speeds.

[4] These tests are outlined in much greater detail in reference (1) and only sufficient information on test method is presented here to provide a basis for the technical discussion.

Presented at the National Meeting of the Applied Mechanics Division of The American Society of Mechanical Engineers, New York, N. Y., June 14–15, 1939.

Discussion of this paper should be addressed to the Secretary, A.S.M.E., 29 West 39th Street, New York, N. Y., and will be accepted until January 10, 1940, for publication at a later date. Discussion received after the closing date will be returned.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

Tests

Photographic Arrangement. Moving-picture cameras were mounted on both sides of the locomotive in a position near the cylinders as shown in Fig. 1. One camera operating at 100 frames per second was mounted on the left side and two cameras with speeds of 100 and of 400 frames per second, on the right side. All were driven by governor-controlled electric motors and remotely operated from batteries and switches located in a car of the train.

Track Conditions. Tests were made on main-line tangent track having 0.18 per cent ascending grade and 100-lb A.A.R.-A rail laid on fully plated 7 × 8-in. hardwood ties. There was at least 12 in. of chat ballast under the ties and this was spot-tamped before the test. Actual values of the modulus of foundation[5] u were measured from tie to tie over a section of the test track and found to vary from 1060 to 3460 lb per in. per in. with an average value of 1500. These values of u are typical of actual conditions existing on present-day well-maintained track.

Locomotives Tested. While six locomotives were tested only two are discussed here.[4] These two locomotives were of the 4–6–4 type used in passenger service and have counterbalance conditions and other characteristics shown in Table 1. Both were identical except that No. 4003 had lightweight reciprocating and rotating parts[6] with a reciprocating weight of 1026 lb per side, an overbalance of 103 lb,[7] and roller-bearing-equipped axles, while No. 3012 had conventional reciprocating parts, 2109 lb per side, friction bearings, and an overbalance of 315 lb.[7]

[5] The modulus of foundation u is defined as the number of pounds of load per linear inch of rail required to depress the rail one inch vertically. The method of measurement was developed by Dr. A. N. Talbot of the University of Illinois in connection with the Special Committee of the A.A.R. on Stresses in Railroad Track and these measurements were made under his direction.

[6] Reciprocating weight includes piston, piston rod, nut, and so on, crosshead and shoes, and the front-end weight of the main rod which is considered as reciprocating.

[7] Overbalance calculated in accordance with A.A.R. method, "Manual of Standard and Recommended Practice," Section F, Association of American Railroads. This is method 1 shown in Table 1.

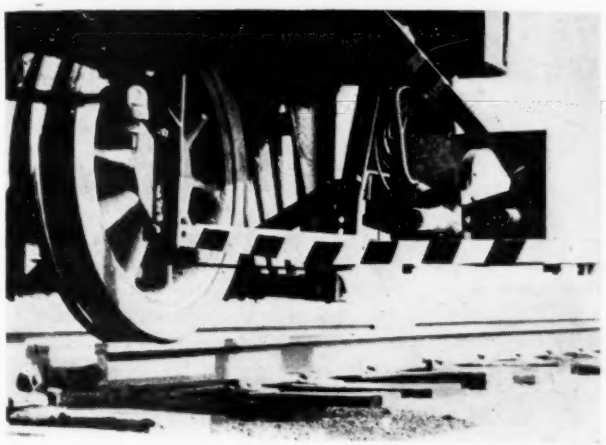

Fig. 1 Camera Arrangement and Location on Extension Platforms in Front of and Below the Locomotive Cylinders

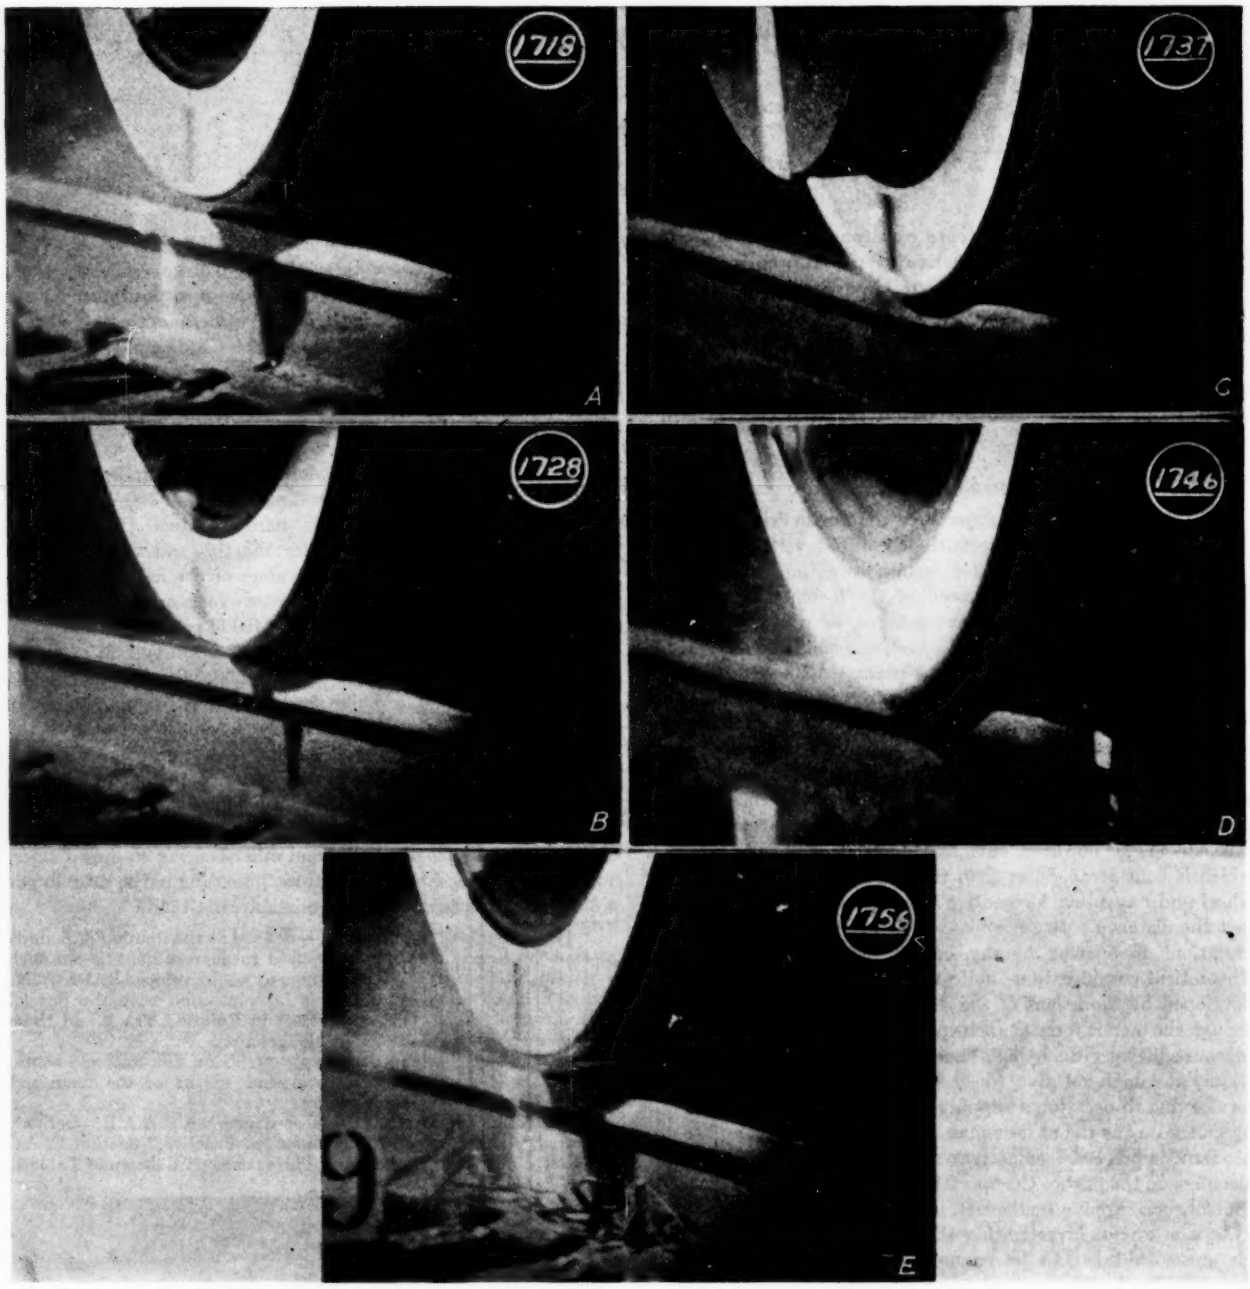

FIG. 2 MAIN DRIVER, LOCOMOTIVE NO. 3012

(Enlargements from 16-mm film taken at 400 frames per sec showing action of wheel on rail for one complete wheel revolution at a slipping speed of 108 mph. Lettered photographs correspond to similarly marked points in Fig. 4.)

Test Procedure. The top of the rail on both sides of the track was greased for a length of from 230 to 504 ft and the locomotive under test, pulling a train of 5 or 6 passenger-equipment cars, entered this greased section at constant speed. Upon entrance of the locomotive into the greased section, the rotative speed of the drivers began to increase. This acceleration (with throttle open) continued even after the locomotive had passed through the greased section due to grease being carried along by the wheels. The locomotive throttle was left open for about 800 ft beyond the greased section to permit slippage of the drivers up to the desired test speed. The motors operating the cameras were started a short distance in advance of entering the greased section. In order to correlate the wheel action with the position of overbalance and the location along the rails, the driver tires were painted with symbols, and markers were placed at frequent intervals along the track so that they were included in the field of view of the cameras.

Results of Tests. These tests definitely indicate forced vibrations of the unsprung weight of the main-axle assembly on the rail, and a condensed statement of the results of tests at several different speeds for each of the two locomotives tested is given in Table 1. Photographs from enlargements of the 16-mm moving pictures for the right side of locomotive No. 3012 at 108 mph slipping speed are shown in Figs. 2 and 3. Fig. 2 shows one

[a] Method 1 is that now recommended by A.A.R. for cross counterbalance—overbalance given in counterbalance plane.
Method 2 same as 1 except correction is made for proper division of main-rod weight into rotating and reciprocating portions—overbalance given in plane of rail.
Method 3 same as 2 except correction is made for proper balance of eccentric rod and crank—overbalance given in plane of rail.
Method 4 by static method—50 per cent of reciprocating balance distributed equally on all drivers which gives 351 lb nominal overbalance on No. 3012 and 171 lb on No. 4003. Overbalance values given by method 3 were used to determine the actual overbalance present.
[b] Two thirds of the eccentric-crank weight was used for No. 3012 and one half for No. 4003.
[c] Speed at which the main driver just leaves the rail.
[d] Average track modulus of 1500 lb per in. per in. was used here to calculate the lifting speeds.

revolution of the main wheel, with the wheel off the rail during most of the revolution, and Fig. 3 shows all three drivers. Figs. 4 and 5 show graphical records of wheel lift from the rail for both locomotives as measured from the 16-mm film projected on a screen.

Discussion of Tests

Comparison of Two Locomotives. It is evident from Table 1 that (*a*) locomotive No. 4003 went into violent vibrations at a speed which is 20 mph faster than for similar vibration of No. 3012 and (*b*) rail kinking resulted from the 7/8-in. wheel lift of No. 3012 but no rail damage developed with 3/4-in. wheel lift of No. 4003. The higher speed required to produce nearly the same wheel lift on locomotive No. 4003 may be explained by the lower overbalance[7]—103 lb for No. 4003 and 315 lb for No. 3012. The manner in which the amount of overbalance influences the speed at which lifting of the wheel begins will be discussed later. Some consideration will be given also to what happens after the wheel leaves the rail but theoretical investigations have not been carried far enough to state whether the amount of rail damage is determined only by the maximum wheel lift. The difference in rail damage may have been due almost entirely to the from 15 to 20 per cent lower wheel lift for locomotive No. 4003, or the difference in the values of overbalance which produced these wheel lifts may also have contributed to the difference in rail damage.

Method of Calculating Overbalance. There is no unanimous opinion among concerned American engineers as to the proper method of calculating the amount of overbalance in main driver wheels. In view of the importance attached to the value in pounds of the overbalance in causing wheel lifting it becomes necessary to define what is meant. The usual meaning of the term overbalance is used here and refers to the weight added over that required to balance the rotating parts; this added weight is used to balance a portion of the reciprocating parts. There are two general methods of calculating overbalance: (*a*) The static method which balances for forces only and neglects couples produced by the out-of-plane positions of various parts of the rotating axle assembly and (*b*) the cross-counterbalance method which balances for both forces and couples and requires considerably more weight in the balance than the static method. It is not intended to discuss the details of these two methods here as earlier writers have covered this field (3, 4, 5, 6, 7, 8). Neither

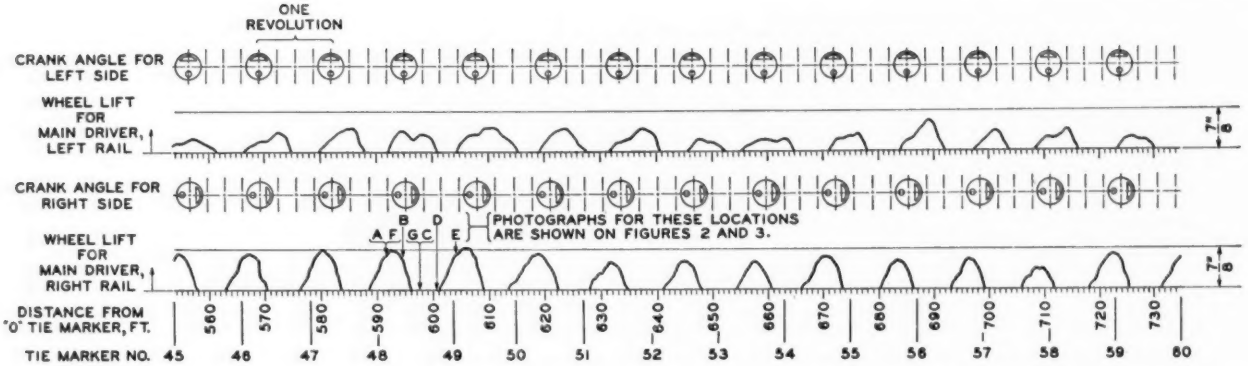

FIG. 4 WHEEL-LIFT CURVES MEASURED FROM MOVING-PICTURE FILM FOR LOCOMOTIVE NO. 3012 AT 108 MPH MAXIMUM SLIPPING SPEED
(Length of greased section, 230 ft, from tie marker 0 to tie marker 19. Train speed, 66 mph. Measurements of lift on left side are only approximate.)

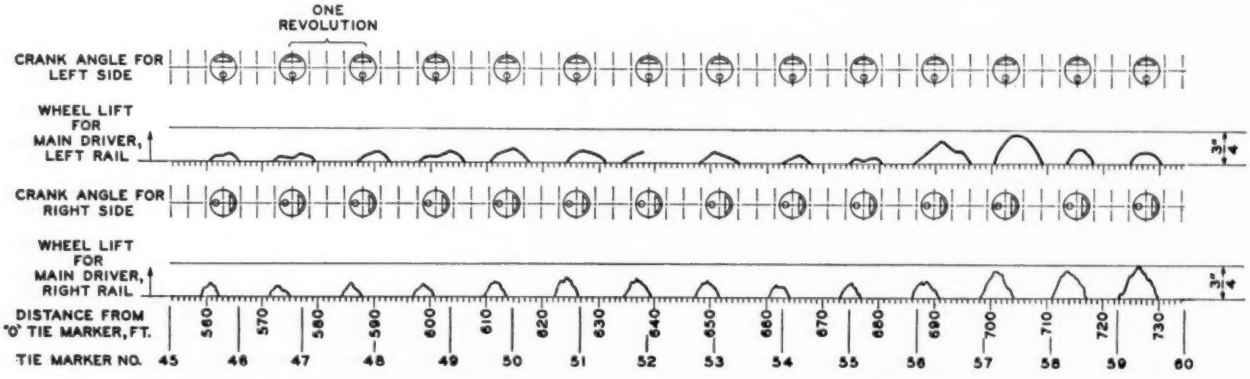

FIG. 5 WHEEL-LIFT CURVES FOR LOCOMOTIVE NO. 4003 AT 128 MPH MAXIMUM SLIPPING SPEED
(Length of greased section, 504 ft, from 274 ft before tie marker 0 to tie marker 19. Train speed, 81 mph. Measurements of lift on left side are only approximate.)

method as generally used is correct. Some defense of this statement is required in view of the thousands of locomotives operating today which are balanced by one of these two methods.

Obviously any driver-axle assembly to be in equilibrium must be balanced for both forces and couples. In this respect the principle of the cross-counterbalance method is correct but assumptions made in carrying out the calculations are often much in error. The static method while basically incorrect is reconcilable; when corrections are made for improper assumptions practiced in usual cross-counterbalance calculations for main drivers, one finds the actual overbalance much higher than when these corrections are omitted, and this actual overbalance may represent a balance condition about as bad as that resulting when the locomotive is statically balanced on the basis of the same improper assumptions.

In order to clarify these discrepancies in balance the two locomotives used in these tests have been calculated for overbalance in accordance with several methods as shown in Table 1. Method 3 is considered a correct statement[8] of the overbalance in these two locomotives as tested. The other methods are given as a matter of information since they are the ones generally followed in practice and with which most engineers are familiar.

Speed at Which Wheel Begins to Lift. The problem of determining the speed at which the driver wheel just begins to leave the rail is treated on the simplified assumption that the locomotive and track structure comprise a system having a single degree of freedom. The vertical motion of the sprung weight of the locomotive is neglected and the problem is reduced to that of determining the motion of the unsprung mass of the axle assembly operating between the driver springs, interposed between the sprung and unsprung masses, and an elastic foundation—the track structure. The overbalance[9] in the wheel produces forced vibrations and if the driving wheel rotates in the region of the natural frequency of this system then the axle assembly will develop severe vibrations on the rail.

Equation 3 and its derivation predicting the speed at which the wheel just begins to leave the rail is given in the Appendix along with remarks relative to the assumptions made. Considering this equation it is apparent that the principal factors influencing the speed at which wheel lifting is initiated are (*a*) modulus of track foundation, (*b*) amount of overbalance, and (*c*) unsprung weight of axle assembly. The relative importance of these factors, for the conditions presented by the locomotives tested and many other locomotives in operation having similar physical characteristics, are shown by curves in Figs. 6 and 7. The influence of various values of modulus of track foundation on the speed at which the wheel just leaves the rail is indicated in Fig. 6 where it is apparent that this speed is little influenced by the track modulus for the larger values of overbalance and that the amount of overbalance has a considerably greater effect on

[8] Footnote in Table 1 partially describes method 3 which includes certain corrections for (*a*) true rotating weight of back ends of main rod and eccentric rod determined from swinging the rods as pendulums per method outlined in reference (5), and (*b*) the eccentric-crank weight was considered acting at its center of gravity instead of assuming an arbitrary allowance acting at crank-pin radius as per methods 1 and 2. It has been assumed without investigation that other rotating parts are properly balanced.

[9] While term overbalance is used throughout this paper the word may be used interchangeably with underbalance, except for the phase of the vibration caused thereby.

this speed. Fig. 7 shows how variations in unsprung weight of the driver-axle assembly influence the speed at which the wheel just lifts for both large and small values of overbalance and spring stiffness of track structure. It is obvious that the value of the unsprung weight has little effect on the speed at which lifting occurs for any stiffness of track shown when the overbalance is large; lower values of overbalance, however, indicate a practical effect on speed for various values of unsprung weight and track stiffness.

After Wheel Begins to Lift. An interesting effect can be observed in Fig. 3 in which the curvature of the rail is shown for two positions of the counterbalance. When the counterbalance is up and the wheel off the rail, the rail is bowed up under the main wheel as shown in (*F*); this condition is emphasized by the straight line drawn tangent to the bottom of the rail head under the front and back driving wheels. Fig. 3 (*G*) illustrates how the rail is bowed down under the main wheel when the counterbalance is down.

Several questions arise as to what happens when the speed is

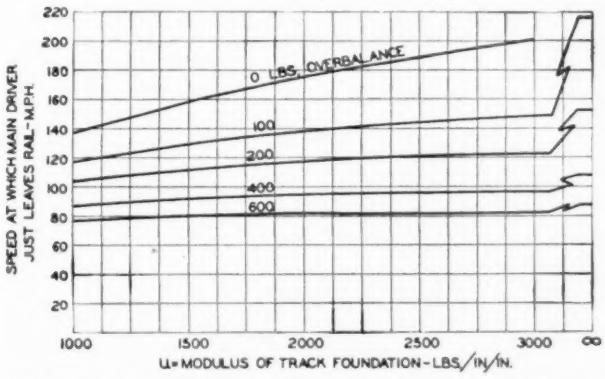

FIG. 6 CALCULATED EFFECT OF AMOUNT OF OVERBALANCE ON SPEED AT WHICH WHEEL JUST LEAVES THE RAIL
(D = 78, R = 14, K = 10,500, S = 24,900, W = 10,900, 100-lb rail.)

increased beyond that required just to cause the wheel to leave the rail such as (*a*) whether the overbalance is in the "up" or "down"[10] position when the wheel lift is about a maximum and (*b*) whether or not higher speeds permit passage through the range of large vibrations and again allow the wheel to remain on the rail without lifting. Sufficient test data do not exist to answer these questions but an attempt has been made to predict theoretically what will happen in the curves of Fig. 8 on the basis of the conditions and assumptions given in the derivation of the formulas presented in the Appendix.

(*a*) Fig. 8 shows, for various speeds and for several values of overbalance, the fraction of a wheel revolution that the wheel is off the rail. It will be noted that each overbalance value is represented by two separate curves, one on the left and one on the right of the single curve for zero overbalance, and that all these curves cross at a common point. In all cases the curve to the left indicates the fraction of the revolution that the wheel is off the rail with the overbalance in the up position, while the right-hand curve indicates that, at higher speeds, the fraction of the revolution that the wheel is off the rail occurs with the overbalance in the down position. The reversal in phase of vibration occurs when the value of this fraction reaches 0.79. It has been reported that actual slipping tests have shown that the balance was in the down position when the wheel lift was a maximum, and Fig. 8 indicates the explanation for this phenomenon. Unfortunately

[10] The "down" position means that the overbalance resultant force is in a direction toward the rail and "up" that the resultant is in a direction away from the rail.

Fig. 8 does not consider the modifying influence that the unknown factors of damping and other conditions mentioned in the Appendix will have on these curves. Oscillator[11] tests could be made to determine these factors so that corrected curves could be obtained representing practical conditions. In such cases it would be expected that the two branches of each curve would be replaced by one single continuous curve lying in the region below the branches of the present curve. The maximum wheel lift,

[11] An oscillator has been designed by the authors which consists of an adjustable out-of-balance-weight device which can be attached to the main crankpin of a locomotive and rotated at various known speeds. The locomotive would be stationary on the track and the out-of-balance rotating weight would produce forced vibrations of the main driver on the rail. Analysis of data from such tests of locomotives on track structures having various spring-stiffness values would permit a determination of more practical curves in Fig. 8. In addition valuable data could be obtained on the effect of other factors influencing stresses in rails produced in service operation of locomotives where wheel lifting is not necessarily involved.

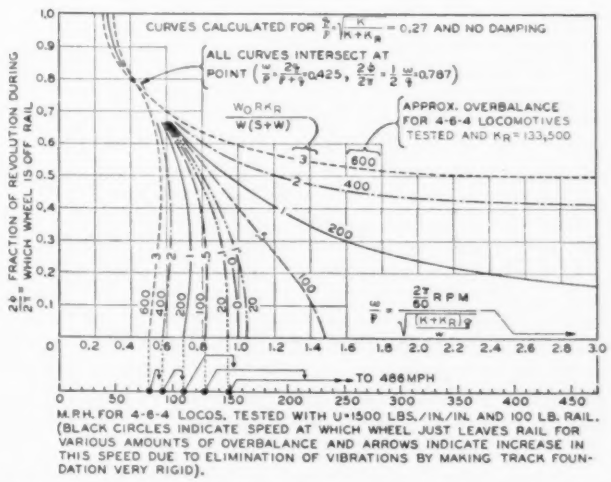

FIG. 8 CALCULATED CURVES FOR VARIOUS AMOUNTS OF OVERBALANCE SHOWING WHEN WHEEL JUST LEAVES RAIL, AND THE FRACTION OF REVOLUTION THAT WHEEL IS OFF RAIL, FOR VARIOUS SPEEDS

(For each overbalance, the curve has two branches except for zero overbalance. For the branch to the left of the curve for zero overbalance, the wheel is off the rail when the overbalance is up. For the other branch, the wheel is off when the overbalance is down. Other branches of the curve are not shown but probably have little practical significance.)

instead of occurring with the overbalance either up or down would lag the disturbing force by an angle which would gradually increase with speed.

(*b*) Fig. 8 indicates that once the wheel has lifted it will not stop lifting except at speeds so high as to be of no practical interest and then only if the overbalance is less than a certain amount. According to Fig. 8 in which friction is neglected, if a locomotive

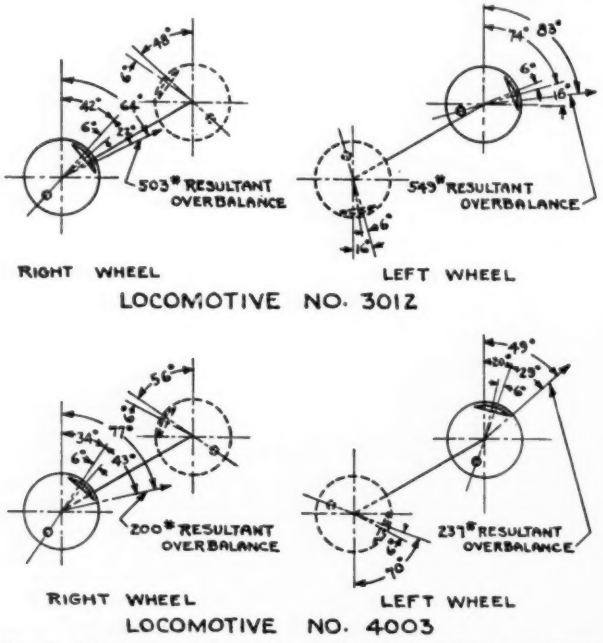

FIG. 9 LOCATION OF OVERBALANCE RESULTANT FORCE IN RIGHT AND LEFT MAIN DRIVERS FOR MAXIMUM WHEEL LIFT OFF RAIL FOR LOCOMOTIVE NO. 3012 AT 108 MPH SLIPPING SPEED AND LOCOMOTIVE NO. 4003 at 128 MPH SLIPPING SPEED

(Each sketch of a pair of wheels indicates by full lines the wheel which is a maximum distance off the rail and dotted lines show relative position of opposite wheel which is not a maximum distance off the rail.)

of the type tested here had about zero overbalance the wheel would start leaving the rail at about 157 mph but would stop lifting after passing through this speed.

The location of the resultant overbalance force acting on each of the right and left main driver wheels for maximum wheel lift off the rail is shown in Fig. 9. It may be noted from the position of the resultant overbalance force that the maximum lift lags behind this force. If higher speeds had been attained than made in these tests it would be expected that the overbalance would lead the maximum lift by an even larger angle than was found in these tests. This phenomenon was discussed in connection with Fig. 8.

Effect on Track and Locomotive. Lifting of the wheel in service does not result in derailment of the locomotive since the other wheels and guiding wheels remain on the rail. The rail was kinked as shown in Fig. 10 by locomotive No. 3012 (overbalance of 315 lb) at 108 mph; at slightly lower speeds the rail was marked on the head as shown in Fig. 11. No rail damage requiring replacement occurred with locomotive No. 4003 in which the overbalance was 103 lb.[7]

The magnitude of the stresses introduced in the rail under such wheel vibrations as shown in Figs. 2 and 3 are not known but even at speeds much lower than that required for the wheel to lift, tremendous variations in rail contact pressure occur during one wheel revolution. This change in pressure is to a large extent due to the resultant of the forces: (*a*) dynamic augment of the overbalance discussed here and, due to angularity of the main rod, vertical components of (*b*) the piston thrust and (*c*) the inertia force on the reciprocating parts.[12] This resultant however is modified by dynamic effects. In the balancing of drivers of locomotives similar to No. 3012 it is sometimes the practice to merely reduce the amount of overbalance conventionally used so as to decrease the force in (*a*) but this procedure does not reduce the resultant rail force in proportion to the change in overbalance or as much as would be anticipated. This is due to the large value of the inertia-force component (*c*) which does not change and the effect it has on the resultant. The desired procedure to reduce the resultant dynamic force on the rail is to decrease the overbalance and at the same time reduce the weight of reciprocating parts as was done with locomotive No. 4003; in this manner both component forces (*a*) and (*c*) are reduced so as to make the resultant dynamic rail force only from a half to a third of the value obtained without reducing the reciprocating weight.

Unbalanced forces have an important effect on locomotive

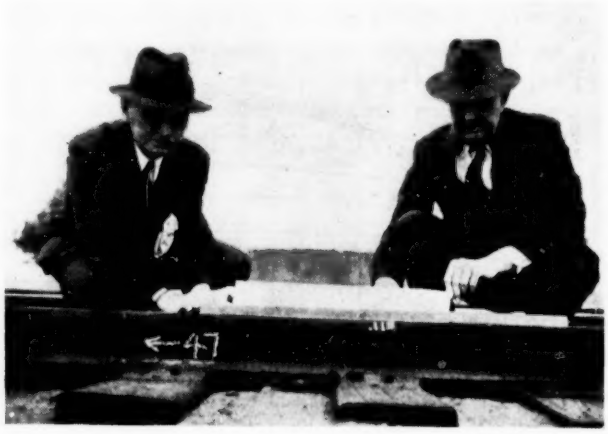

FIG. 10 RAIL KINK PRODUCED BY LOCOMOTIVE NO. 3012 AT 108 MPH

FIG. 11 RAIL MARK PRODUCED BY LOCOMOTIVE NO. 3012 BEFORE REACHING 108 MPH

operation and maintenance, as well as on track structure but the limitations of overbalance and weight of reciprocating parts for various degrees of difficulties and expense involved with locomotive and track are unknown. In this respect lighter reciprocat-

[12] The effects of (*b*) and (*c*) on wheel vibrations have not been considered here because their frequency is twice that of (*a*) and their influence may be small except for low overbalance values. These forces are shown by curves in reference (1) which show the component as well as the composite forces acting on the rail and unbalanced forces tending to shake the locomotive.

ing parts also reduce the unbalanced distributing forces[12] on the locomotive.

Acknowledgment

Considerable credit is due T. V. Buckwalter, vice-president of Timken Roller Bearing Company, under whose direction this photographic study was made. The tests were actually made under the general direction of H. H. Urbach, mechanical assistant to the executive vice-president of the Chicago, Burlington and Quincy Railroad, and F. Zeleny, engineer of tests. Considerable calculating work was done by R. Morgan of the Timken railway engineering department. Valuable discussions were also had with Professor S. Timoshenko and Professor J. Ormondroyd.

Appendix

Figs. 6, 7, and 8 are based on calculations made from theoretical equations for the vertical motion of an unbalanced locomotive driving wheel. In the derivation of these equations, several simplifying assumptions are made. Friction is assumed to be zero and the mass of the rail and of moving parts of the track foundation are neglected and accordingly there can be no energy loss due to impact when the wheel strikes the rail after having lifted from it. It is assumed that the vertical motion of the sprung weight of the locomotive is negligible in the speed range considered. The unsprung weight of an axle, a pair of wheels, and so on, is divided into two equal weights assumed to be concentrated, one in the plane of each rail. Any vertical movement of the driver springs as a whole which may exist due to functioning of the equalizer system is neglected. Vertical forces which act on a main driver due to angularity of the main rod combined with piston thrust due to steam pressure, and inertia forces on the reciprocating parts are neglected. The rail on its foundation is assumed to have a linear load-deflection curve and the effect of rail deflection due to one driver on vibrations of the other drivers is neglected. It is also assumed that the driver tires are perfectly round and that no irregularities are present in the rail surface.

With these and other assumptions, the problem of the vertical motion of a driver wheel due to unbalance reduces to the case of motion of a single mass held between two compressed springs with a sinusoidal disturbing force applied to the mass. For a certain amplitude of vibration, the mass could intermittently lose contact with one of the springs and this would correspond to the lifting of a driver wheel from the rail.

Notation

W = unsprung weight per driver wheel, lb
S = sprung weight per driver wheel, lb
K = driver-spring stiffness, lb per in.
K_R = stiffness of rail on its foundation, assumed to be the same at all points, lb per in.
g = acceleration due to gravity, in. per sec per sec
R = crank radius, in.
D = driver diameter, in.
W_O = unbalanced weight at crank radius, per driver wheel in plane of rail, lb
ω = angular velocity of driver, assumed to be constant, radians per sec
ωt = angular displacement of driver taken as zero when the unbalance is on the vertical center line and above the horizontal center line of the wheel, radians
x_1 = upward displacement of driver from its position of rest for the fraction of a revolution during which the wheel is on the rail, in.
x_2 = upward displacement of driver from its position of rest for the fraction of a revolution during which the wheel is off the rail, in.
ϕ = half the angle during which the wheel is off the rail, radians.

In addition, the following abbreviations will be used

$$p = [(K + K_R)g/W]^{1/2}$$

$$q = (Kg/W)^{1/2}$$

so that $$q/p = [K/(K + K_R)]^{1/2}$$

The differential equation of motion for the wheel when it is on the rail and rotating at a constant speed is

$$\frac{W}{g}\frac{d^2x_1}{dt^2} + (K + K_R)x_1 = \frac{w^2RW_O}{g}\cos \omega t$$

or

$$\frac{d^2x_1}{dt^2} + p^2x_1 = \frac{\omega^2RW_O}{W}\cos \omega t$$

The solution of this equation is (9)

$$x_1 = A \cos pt + B \sin pt + \frac{RW_O}{W}\frac{\omega^2}{(p^2 - \omega^2)}\cos \omega t \quad \ldots [1]$$

where A and B are constants of integration. If the wheel does not leave the rail during any part of a revolution (9) and the vibrations of the wheel have reached a steady state, then A and B are zero so that

$$x_1 = (RW_O/W)\ [\omega^2/(p^2 - \omega^2)]\cos \omega t$$

and

$$(x_1)_{max} = (RW_O/W)\ [\omega^2/(p^2 - \omega^2)]$$

If the wheel just leaves the rail instantaneously once during each revolution, then the value of $(x_1)_{max}$ must equal the rail deflection under the driving wheel due to the static wheel load or

$$(RW_O/W)\ [\omega^2/(p^2 - \omega^2)] = (S + W)/K_R$$

and from this equation, the angular wheel velocity at which the wheel will just leave the rail is

$$\omega = \left\{\frac{(K + K_R)g}{W + [K_R/(S + W)]RW_O}\right\}^{1/2} \quad \ldots\ldots [2]$$

which corresponds to a train speed in miles per hour of

$$\text{mph} = \frac{D}{35.2}\left\{\frac{(K + K_R)g}{W + [K_R/(S + W)]RW_O}\right\}^{1/2} \quad \ldots\ldots [3]$$

The curves of Figs. 6 and 7 were calculated from Equation [3].

For higher speeds, the wheel will be off the rail during a portion of each revolution. The constants A and B in Equation [1] will no longer be zero and, assuming that a steady state of vibrations has been reached, can be determined from the conditions

$x_1 = (S + W)/K_R$ when $\omega t = \phi$ and $dx_1/dt = 0$ when $\omega t = \pi$.

Then

$$x_1 = \frac{\left[\frac{S + W}{K_R} - \frac{RW_O}{W}\frac{\omega^2}{(p^2 - \omega^2)}\cos \phi\right]}{\cos[(p/\omega)\ (\pi - \phi)]}\cos\left[\frac{p}{\omega}(\pi - \omega t)\right] + \frac{RW_O}{W}\frac{\omega^2}{(p^2 - \omega^2)}\cos \omega t \quad .. [4]$$

and this equation is applicable only from $\omega t = \phi$ to $\omega t = 2\pi - \phi$.

When the wheel is off the rail, from $\omega t = -\phi$ to $\omega t = \phi$, the equation of motion is

$$\frac{d^2x_2}{dt^2} + q^2x_2 = \frac{\omega^2 RW_O}{W}\cos\omega t - \frac{g(S+W)}{W}$$

When this equation is integrated and the conditions

$x_2 = (S+W)/K_R$ when $\omega t = \phi$, and $dx_2/dt = 0$ when $\omega t = 0$ are applied to determine the constants of integration, it is found that

$$x_2 = \frac{\left[\frac{S+W}{K_R} + \frac{S+W}{K} + \frac{\omega^2}{(\omega^2 - q^2)}\frac{RW_O}{W}\cos\phi\right]}{\cos(q\phi/\omega)}\cos qt - \frac{S+W}{K} - \frac{RW_O}{W}\frac{\omega^2}{(\omega^2 - q^2)}\cos\omega t \quad [5]$$

One condition remains to be satisfied, namely, that the vertical velocity of the wheel obtained from Equation [4] shall equal that obtained from Equation [5] when $\omega t = \phi$, i.e., $dx_1/dt = dx_2/dt$ when $\omega t = \phi$. To satisfy this condition it is found that

$$\frac{K_R RW_O}{W(S+W)} = \frac{\left(\frac{p^2}{\omega^2} - 1\right)\left\{\tan\left[\frac{p}{\omega}(\pi - \phi)\right] + \frac{p}{q}\tan\frac{q\phi}{\omega}\right\}}{\cos\phi\left\{\tan\left[\frac{p}{\omega}(\pi - \phi)\right] - \frac{q}{p}\left(\frac{p^2 - \omega^2}{\omega^2 - q^2}\right)\tan\frac{q\phi}{\omega}\right\} + \frac{\omega}{p}\left(\frac{p^2 - q^2}{\omega^2 - q^2}\right)\sin\phi} \quad [6]$$

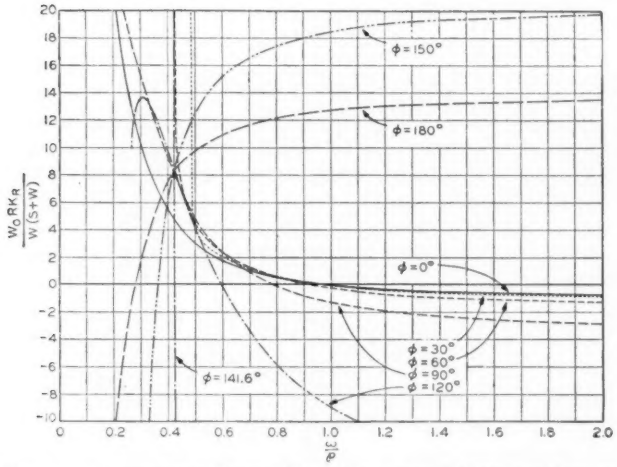

FIG. 12 CALCULATED CURVES FROM EQUATION [6] USED TO OBTAIN FIG. 8

(Only one branch of each curve is shown. Other branches in addition to the branch shown are believed to have little practical significance for the problem of vibration of a locomotive driving wheel.)

and this equation can be solved easily for the value of $K_R RW_O/W(S+W)$ for any assumed values of ϕ and ω/p after assigning a value to the constant $q/p = [K/(K+K_R)]^{1/2}$.

In Fig. 12, values of $K_R RW_O/(S+W)W$ are plotted against ω/p for values of ϕ from 0 to π. These curves are for the case of $q/p = 0.27$ or $K/K_R = 0.0787$ which corresponds to $K = 10{,}500$ lb per in. and $K_R = 133{,}500$ lb per in.; the latter figure is the rail stiffness for 100-lb rail and a track modulus of 1500 lb per in. per in. track modulus. Some of the curves have other branches than the one shown but these additional branches are omitted to simplify the figure and are believed to have little practical significance since they occur at speeds less than that at which the wheel just leaves the rail, except when $K_R RW_O/(S+W)W$ is too large to be of interest. The curves of Fig. 12 were used as a means of obtaining Fig. 8, the significance of which is discussed in the body of the paper. In Fig. 8, two branches of the curves are shown for each value of $K_R RW_O/(S+W)W$ and additional branches are omitted as in Fig. 12. Having Fig. 8, it would be possible to return to Equations [4] and [5] and calculate the maximum wheel lift and the maximum rail depression as well as the value of the rail load corresponding to this depression. However such investigations have not been completed and it may be more important first to obtain curves such as those of Fig. 8 for less idealized conditions, perhaps with some values assumed for friction and the energy loss due to impact when the wheel strikes the rail.

Discussion

The Determination of the Expansion Forces in Piping by Model Test[1]

EVERS BURTNER.[2] Load-deflection tests of several one-plane expansion bends were made in connection with the undergraduate thesis of William Budd and David Cooper, 1936, Department of Naval Architecture and Marine Engineering, Massachusetts Institute of Technology. The agreement between the calculations and measured deflections was satisfactory. While the loading to represent fixed-end conditions was much simpler than the ingenious one outlined by the author, particular care was taken in the construction of the model bends. They were annealed after bending, being packed in cast-iron chips to avoid formation of scale. It would be interesting to learn whether the Westinghouse Electric & Manufacturing Company has found it advisable to use similar care in constructing more complicated three-dimensional bends.

It is difficult to fix the ends of the tubing without introducing high local stresses at this point. From the appearance of Fig. 6, the writer assumes that this end of the pipe bend is held by the friction or press fit of the pin-supported bushing.

F. M. HILL.[3] The model method for determining forces and moments in three-dimensional pipe runs will unquestionably appeal to the practical-minded engineer because of its slide-rule simplicity and general reliability. The solution of the branch problem is now within easy reach of the designing engineer.

The foundation for work with models was laid by the work already done in the field of mathematics and graphics by such men as Hovgaard, Crocker, McCutchan, Wahl, Karelitz, Marchant, Shipman, Mitchell, Cocks, and others. It is upon their work that the intelligent development and use of the model method stands.

The question arises, to what extent has the author verified his model answers with actual installations or with calculated solutions? This is an important consideration in the minds of inquiring engineers.

The writer is in general agreement with the author's method of translating the forces and moments of the model to those of the actual pipe run. However, his statement: "If the model were exactly to scale and of the same material as the full-size pipe, the forces on the full-size pipe would simply equal the model forces divided by the scale of the model," appears to be misleading or at least incomplete. Should it not be amplified to include moments, temperature, and deflections, since these are essential factors in every problem?

The following revision is suggested: If the model were exactly to scale in all dimensions, of the same material, at the same temperature, and deflected the scale amount, the forces and moments on the full-size pipe would equal the model forces and moments divided by the scale squared and the scale cubed, respectively.

Since departures are generally made in one or more of the factors mentioned, it is quite necessary that the operator understand the fundamental mathematical relationships.

Concerning the experimental error mentioned by the author in the use of his model, the writer's attention has been drawn to Fig. 1, showing a model pipe run set up for testing. It appears that small screws have been used at both ends of the pipe to secure it to the slide base and to the measuring head or frame. Can these screws be depended upon for positive fixation? The sliding head appears to be tilted at an angle that would hardly correspond to the type of pipe run being tested. The bend in the pipe adjacent to the measuring head appears to be considerably flattened in cross section.

The writer has been working for several months with a model-testing and analyzing device, differing considerably from that of the author. Different scales have been used deliberately to obtain exaggerated readings, for the purpose of reducing the relative error in taking measurements, and to make various influences more pronounced for analytical observations. Solid steel die-drawn rods approximately $^1/_4$ in. in diameter, bent to shape at a red heat and further stress-relieved by heat-treating, have given results well within the practical limits of power-plant designing. The device will accommodate tubing as well as solid rods. No practical advantage, however, has been found in the use of tubing over solid rods, while considerable advantage has been found in the use of rods which make it possible to duplicate results by testing several models made in duplicate. The uniformity of cross section of die-drawn rods, together with the uniformity with which they can be bent to shape, makes their use an outstanding feature.

The reliability of the model method in my experience is one of its outstanding qualities. The model-testing and analyzing device, which the writer has developed, is particularly well adapted to demonstrating visually the influence or the effect produced by various changes in loadings, and the relative importance of the various loadings.

From the standpoint of actual practice, several factors enter the problem which determine the degree of accuracy to be sought in any solution. A mathematical solution to five significant figures is obviously not consistent when applied to a pipe run having a wall thickness variation of 12.5 per cent, the allowable mill tolerance, which may or may not result in considerable eccentricity. The cross section of the pipe in a bend may be quite elliptical and eccentric instead of round and concentric as assumed in mathematical formulas.

The time element and the attendant quality of creep in the metal gradually changes the initial stresses toward an equilibrium which may be at considerable variance with answers obtained by any method of solution. The actual pipe run also differs from the run of the problem usually assumed, in that the actual run is stiffened by the installation of valves and restraining and supporting pipe hangers. Ends assumed to be fixed are actually only partially fixed. Finally, the last weld or connection made in the pipe run during construction may introduce stresses and strains of considerable magnitude.

Conservatively speaking, it has been the writer's experience that a day spent with the model-testing and analyzing device on a three-dimensional run will produce more answers of a higher degree of reliability and of greater practical accuracy than one to three weeks spent with calculation methods by the average

---

[1] Paper by Harold W. Semar published in the March, 1939, issue of the JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 61, 1939, p. A-21.

[3] Engineer, Commonwealth & Southern Corporation, Jackson, Mich. Mem. A.S.M.E.

engineer. The results, to say the least, have been most satisfactory.

Whatever method is employed to determine stresses and strains in a pipe run, it should be a reliable standard on which rational judgment can be based. In the writer's opinion the model method is the practical engineer's handy tool for this purpose. In the solution of branch problems it is his only workable method at the present time.

WILLIAM HOVGAARD.[4] In view of the complications and elaborate calculations associated with a theoretical determination of the expansion stresses and forces of even an idealized piping system, engineers will undoubtedly welcome a mechanical method such as the one here proposed, provided the results are reliable and sufficiently accurate.

The apparatus described in the paper seems to be simple and robust and the mathematics is simple. The principal source of difficulties in pipe tests lies in obtaining absolute fixity of the ends of the pipe, while at the same time obtaining a record of the reactions. These difficulties seem to be overcome here.

The movable end of the model pipe is clamped in what appears to be a solid block bolted to a tool slide. Thus it can hardly be subject to any angular or linear deflection.

At the fixed end the twofold object of holding the pipe in an angular direction and of measuring the forces is attained ingeniously by employing the same struts or pins, which hold the pipe fixed in direction, as transmitters of the forces, which it is desired to measure. It is not quite clear how R_y is obtained while at the same time the end of the pipe is prevented from moving in its own direction.

It would be interesting to know whether a comparison has been made between the results obtained by a model and those obtained by a purely theoretical calculation.

G. B. KARELITZ.[5] It may be of interest to consider the case of high-pressure steam pipes. For such pipes the ratio

$$\lambda = tR/r^2 = t/r \times R/r$$

is of a definite order of magnitude. R/r is usually about 10 (R equals five diameters of the pipe), while t/R is from $^1/_8$ to $^1/_4$. This gives values of λ from 2 to 2.5. The coefficient of increased flexibility is $k = \dfrac{10 + 12\lambda^2}{11 + 12\lambda^2}$; it varies from $k = 1.1$ for $\lambda = 2$, to $k = 1.11$ for $\lambda = 2.5$. The variation is small. Therefore, if the author's formula gives, say, a scale factor $s = 18.5$, no appreciable error would result in taking a convenient scale factor, such as $s = 20$, close to 18.5. Of course, this does not hold for low-pressure thin-walled pipes.

The writer was invited by Sanderson and Porter to determine the expansion forces and stresses for the high-pressure pipes of an installation comprising three leads from the boilers to a distributing manifold and two leads from the manifold to the turbine throttles. The computation tables[6] referred to by the author were set up by the writer for that purpose. The values obtained for the five pipes will be of interest in comparison with those given in the paper. The pipes were 12.75 in. outside diameter; thickness of wall $t = 1.294$ in.; the bends were of 60 in. radius; temperature of steam 935 F, i.e., close to the conditions obtaining in the paper. The pipes were considered without cold spring, but the motion of the boiler headers and turbine throttle as submitted by the respective manufacturers was taken into account.

The forces and moments are given in Table 1.

TABLE 1 FORCES AND MOMENTS IN HIGH-PRESSURE PIPING SYSTEM

Reaction		Lb P_x	Lb P_y	Lb P_z	Lb-in. M_{xy}	Lb-in. M_{yz}	Lb-in. M_{zx}
Boiler leads	No. 2	1520	900	220	705100	120100	20400
	No. 4	680	1180	370	368900	204000	16600
	No. 6	110	1370	430	39500	213500	30800
Turbine leads	No. 1	110	300	1190	33000	2550	110000
	No. 2	470	470	920	7400	123400	1700

NOTE: The signs, i.e., the directions of the forces and moments, are omitted.

The difference between the first three pipes and the last two is that the first ones are very much longer. The magnitudes of the force components (lateral, axial, and vertical) are of the same order as reported by the author, within 2000 lb. These are within the limits usually allowed by manufacturers of turbines or boilers. However, the moments tending to bend or twist the pipe at the header are much larger in the case of the longer boiler leads.

The boiler-builder's specification called for zero twisting moment at the superheater header, which would mean elaborate clamping of the pipe to take up the twist. Joint action resulted in a corresponding change in the design of the boiler to take care of the twisting and bending moments on the superheater header. To the writer's knowledge there has been no leakage of steam from the superheater header in these three boilers.

When a company is confronted frequently with the computation of end reactions of pipes, it would no doubt be economical to build and operate the instrument suggested by the author. However, if only occasional determinations occur, then it is more economical to obtain the answer by computation. In the discussion of the paper[6] in which the writer's tables were published, it was brought out that a number of concerns and individuals were occupied working out similar schemes for computation. "A similar, although somewhat different method has been developed by H. C. E. Meyer, chief engineer of Gibbs & Cox, Inc.;" "...for a number of years, the Westinghouse Electric & Manufacturing Company has used a method very similar to the one given in this paper;" D. R. Rosenheim of M. W. Kellogg Company states that they "are now able to handle more complex pipe lines, involving three or more points of fixation and similar problems in a reasonable length of time." It is reasonable to assume that these methods may be better than the plates set up by the writer. The publication of these methods would be of service to the art.

J. H. MARCHANT.[7] The author's method is particularly desirable for organizations whose demands justify the cost of such model apparatus and the services of an expert to operate it. While favorably impressed with the model method proposed, the writer remains of the opinion that two different methods should be used for the determination of the expansion forces and moments in pipe lines. In this case the author's method should certainly be included.

The method which is used for the determination of the model deflection constants R_x R_y, etc., is interesting. Here, although it appears at first glance the author has assumed that the deflection constants are valid over the range of the actual displacement of the end of the prototype ($e_a = 2.99$ in.), in reality he merely assumes that they are valid in the range 0 to 0.4 in., which is probably well within the elastic range of the model.

[6] "End Reactions and Stresses in Three-Dimensional Pipe Lines," by G. B. Karelitz and J. H. Marchant, JOURNAL OF APPLIED MECHANICS, Trans. A.S.M.E., vol. 59, 1937, p. A-68.

[7] Associate Professor of Mechanical Engineering, Connecticut State College, Storrs, Conn. Mem. A.S.M.E.

In an effort to check the results, the writer has computed the expansion forces and moments exerted by the actual pipe line the author used, by the method referred to in footnote 6 on page A-186. The elastic equations of this pipe line are as follows:

(1) $-131{,}698\ P_x + 140{,}060\ P_y - 1404\ P_z + 9\ M_{yz} + 6.3\ M_{zz} + 1295\ M_{xy} = 0$

(2) $359{,}615\ P_x - 288\ P_y - 144{,}849\ P_z + 9\ M_{yz} + 1289\ M_{zz} + 6.3\ M_{xy} = 0$

(3) $1692\ P_x - 330{,}099\ P_y + 118{,}137\ P_z + 1232\ M_{yz} + 9\ M_{zz} + 9\ M_{xy} = 0$

(4) $159{,}216{,}945\ P_x - 19{,}586{,}892\ P_y - 46{,}411{,}692\ P_z + 1692\ M_{yz} + 359{,}618\ M_{zz} - 131{,}596\ M_{xy} = 21{,}084 \times 10^6$

(5) $-19{,}084{,}038\ P_x + 135{,}216{,}954\ P_y - 39{,}114{,}902\ P_z - 330{,}102\ M_{yz} - 288\ M_{zz} + 140{,}063\ M_{xy} = -38{,}306 \times 10^6$

(6) $-46{,}411{,}666\ P_x - 39{,}114{,}154\ P_y + 45{,}527{,}440\ P_z + 118{,}139\ M_{yz} - 144{,}847\ M_{zz} - 1404\ M_{xy} = 20{,}440 \times 10^6$

The checks for these equations, as based on Maxwell's reciprocal theorem, are given in Table 2.

TABLE 2 EQUATION CHECKS BASED ON MAXWELL'S RECIPROCAL THEOREM

$P_{x1}:M_{xy4}$	—131698:	—131596	$P_{y3}:M_{yz5}$	—330099:	—330102	$M_{yz1}:M_{xy3}$	9.0 :	9.0
$P_{x2}:M_{xz4}$	359615:	359618	$P_{z1}:M_{xy5}$	—1404:	—1404	$M_{yz2}:M_{xz3}$	9.0 :	9.0
$P_{x3}:M_{yz4}$	1692 :	1692	$P_{z2}:M_{xz5}$	—144849:	—144847	$P_{y4}:P_{z5}$	—19586892:	—19084038
$P_{y1}:M_{xy5}$	140060:	140063	$P_{z3}:M_{yz6}$	118137:	118139	$P_{z4}:P_{x6}$	—46411692:	—46411666
$P_{y2}:M_{xz5}$	—288:	—288	$M_{xz1}:M_{xy2}$	6.3 :	6.3	$P_{x6}:P_{y4}$	—39114902:	—39114154

For purposes of comparison, the results of the writer's calculations are given, together with those of the author, in Table 3.

TABLE 3 FORCES AND MOMENTS EXERTED BY PROTOTYPE PIPE

Reaction	Semar	Marchant	Variation, per cent
P_x	470 lb	495 lb	—5
P_y	—980 lb	—941 lb	—4
P_z	1120 lb	949 lb	+18
M_{xy}	145000 lb-in.	155674 lb-in.	—7
M_{yz}	—318000 lb-in.	—344844 lb-in.	+8
M_{zz}	—9600 lb-in.	—29923 lb-in.	+68

The author's paper has been studied carefully without discovering any error in his model criteria or in his method. True, the scale fidelity between model and prototype is not perfectly maintained, i.e., the small bend in the model of $^7/_8$ in. radius corresponds to 17.5 in. radius rather than the required 18 in. radius in the prototype; and one straight section in the model corresponds to 137.5 in. rather than the required 138 in. in the prototype. However, these departures from geometrical similarity between model and prototype in the author's work are not sufficient to account for the discrepancies between the writer's results and those obtained by him, i.e., 18 per cent and 68 per cent in the cases of P_z and M_{zz}, respectively. Further, λ has obviously not been maintained in the model due to the difficulty of making sharp bends in the model without flattening the pipe. (It is suggested that a low-fusion alloy be used, instead of sand, in making these bends.)

The most logical explanation for the departure in results lies in the method used by the author for the determination of his so-called model deflection constants. When it so happens, as it does in the case of R_{zz}, that the calibration curve has a small slope (—2.1), the determination of this particular model deflection constant is questionable. This possible error in R_{zz} introduces a proportionally large error in M_{zz} and has a smaller effect on P_z. This observation is in agreement with results given in Table 3. The writer's calculations, on the other hand, may be in error, since there are six coefficients without any check within themselves in the equations. However, every precaution has been used in executing them.

M. S. NOYES.[8] This paper leaves one with a feeling of wonder as to why some easier and more direct method of manipulating and measuring the reactions of the model section of piping has not been devised and applied to the author's setup.

The writer has had opportunity to view another piece of apparatus developed for the same purpose which had more accurate, direct, and visual means for obtaining the reactions and observing the behavior of the section of model piping under test. Surprisingly close agreement was obtained with values found by the customary formulas for calculation of moments, forces, and stresses in piping via thermal expansion.

Perusal of the subject paper and observation and discussion of the apparatus just mentioned would seem to indicate that the value of the method can be reaped most directly by the turbine manufacturer who is concerned with the effect of thermal expansion reactions upon his turbine main steam connection. The second and more dubious value lies in the ability of the apparatus to check calculations on single-branch piping sections and to provide the end reactions for making the calculations on multibranch sections of piping. No saving in calculations by the piping designer is involved as in every case the calculations must be made in order to determine the fiber stress in the full-sized piping.

E. O. WATERS.[9] The calculation of piping stresses and deflections is notoriously cumbersome, even though it involves nothing more than patient application of addition, subtraction, multiplication, and division. Designers in the power-plant and process-industry fields should accordingly study with interest any method that promises to lighten the labor of piping computations. The model setup described in the present paper is relatively simple; it requires no equipment beyond that available in the usual machine shop and toolroom; instrument indications are large enough to be read accurately; the procedure has been in use and is, therefore, presumably on a sound practical basis.

The author has been extremely modest as to claims for the value of his method and goes only so far as to emphasize its value for determining end moments and reactions. This is natural since the organization that has been using the method is doubtless more interested in the effect of the pipe on the anchorage than that of the anchorage on the pipe. It is obvious, however, that the method makes it possible to determine the forces and couples at any arbitrary section of the pipe line, so that the pipe stress itself may be calculated.

By way of criticism, the writer believes it worth-while to point out that the scale factors, which are used for extending the model reactions and moments to the full-size values, accurately represent the effect of flattening of the section at bends and the effect of bending actions, but are slightly in error as regards longitudinal extension, which is directly proportional to the first power of the length and inversely proportional to the cross-sectional area instead of the moment of inertia. This error may be eliminated by choosing R_m such that $\frac{R_m}{R_a} = s = \left(\frac{r_m}{r_a}\right)^2 \frac{t_a}{t_m}$, which takes care of the flattening effect and in addition, by making $s = \frac{\rho_m}{\rho_a}$, where ρ = radius of gyration of pipe section. Since for ordinary piping ρ varies approximately as r and is independent of t, this reduces the requirements to

[8] Engineer, Design Division, Bureau of Engineering, Navy Department, Washington, D. C. Mem. A.S.M.E.

[9] Associate Professor, Mechanical Engineering, Yale University, New Haven, Conn. Mem. A.S.M.E.

$$\frac{R_m}{R_a} = s, \qquad \frac{r_m}{t_m} = \frac{r_a}{t_a}$$

In most layouts, it is to be expected that direct extensions will be small in comparison with bending displacements, and the ratio of pipe radius to wall thickness in the model will be reasonably close to that in the full-size pipe; hence the error in the author's formula is of the second order and it may be neglected with safety.

As an example, consider a full-size and model pipe of the dimensions given in Fig. 5 of the author's paper, for which $s = 0.0484$, $\frac{r_m}{t_m} = 4.3077$, $\frac{r_a}{t_a} = 4.3588$; the full-size pipe consisting of a 3-ft radius quarter bend, followed by a 24-ft tangent. The pipe is anchored at one end of the bend, and the far end of the tangent is displaced lengthwise without rotation. Then the full-size and model forces at the anchorage are actually in the ratio (E_m assumed the same as E_a):

Axial force, 19.511531
Transverse force, 19.512600
Moment, 403.060854

The author's formula gives

Axial force, 19.506731
Transverse force, 19.506731
Moment, 402.981686

As far as torsion is concerned, the conversion from model to full-scale loads appears to be precise, provided, however, that Poisson's ratio is the same for both, at the temperatures involved.

Author's Closure

The author feels that the method of clamping the ends of the model was not clearly shown in the paper. This was done by extending the model tubing beyond the theoretical point of fixity. A tight-fitting plug was inserted into this extension so that the four clamping screws did not collapse the tubing. The four clamping screws can be seen on the movable end of the model in Fig. 1 on the first page of the paper. The hole in the clamping piece which carried the model end was relieved beyond the first pair of clamping screws so that the tubing was unrestrained beyond that point.

Bends in the tubing have been made by packing the tube with sand and bending the tubing around a die without heating. The low-fusion alloy suggested by Mr. Marchant has been tried and found satisfactory.

It has been pointed out in the discussion that slight departures from the scale criteria in the construction of the model are of little importance, and that the departures of the prototype from the theoretical dimensions due to fabrication and erection tolerances may be considerable. Refinements in the testing procedure and in the construction of the model to approach more closely the result obtained by a calculation of a mathematically precise system are not warranted to obtain a practical solution of a piping problem.

Mr. Marchant's explanation of the difference between his calculated values and the author's test values is correct. With the model-testing method, it is possible to have a large percentage error in the determination of a force or moment which is small in relation to the other forces and moment. In the case of M_{zz} in which the discrepancy is large, the deflection constant R_{zz} is roughly 3 and 6 per cent, respectively, of the other two moment deflection constants and is therefore liable to a considerable percentage error. However, a large percentage error in a small force or moment is of little practical significance.

Analysis of Effect of Wire Curvature on Allowable Stresses in Helical Springs[1]

J. R. Finniecome.[2] The author has referred to Röver and Göhner. The purpose of the writer's contribution is to give a comprehensive survey of the theory, formulas, and tests of the five principal authorities on the design of closely coiled springs.

Röver's Theory.[3] The most striking classical advances in the mathematical theory of the stresses in springs are to be found in Röver's pioneer work, published as early as 1913. It is unnecessary here to emphasize its importance, for it contains a wealth of original information. It would be a mistake to underrate its immense value. Several interesting facts emerge from a close examination of this authoritative analysis. We find that the maximum shear and bending stresses are also a function of the curvature of the spring, the cross section of the wire, the radius of the wire in the case of a circular cross section, and also of the pitch angle.

Wahl's Theory.[4] In 1929 increased interest was taken in Röver's advanced theory by Wahl for he published additional formulas for a pitch angle equal to zero. The latter's formula for the maximum-shear stress is by no means simpler than Röver's for a zero pitch angle.

Honegger's Theory.[5] In the last few years renewed interest and controversy have centered around the stress theory of springs, and it is important to mention here also the mathematical analysis and test of Honegger in 1931. His work is a worthy addition to this literature for his formulas correct for the displacement of the actual center of rotation of the fiber from the geometrical cross section of the wire during the loading and the compression of the spring. Neither Röver nor Wahl has allowed for this correction.

Göhner's Theory[6] *and Bergsträsser's Formulas.*[7] Göhner's lengthy and rather involved mathematical analysis was first published in 1930 and then continued in 1932. It contains a wealth of interesting information and is an extremely valuable study of the subject. It will, however, be found that the formulas when compared with those of the other authors are too complicated. Reference to Tables 1 and 2 shows this very clearly.

Göhner's formulas were simplified mathematically in a very ingenious manner by Bergsträsser (Tables 1 and 2) in 1933 and these are now of real practical value for numerical evaluation. Göhner's formulas are now in general use in Germany, special charts having been produced to reduce the mathematical work. It will be found that the numerical values of Bergsträsser agree closely with Göhner, the discrepancy being very minute.

Comparison of Stress Factors of Five Authors. The formulas

TABLE 1 FORMULAS FOR MAXIMUM-SHEAR- AND BENDING-STRESS FACTORS FOR HEAVY CLOSE-COILED SPRINGS OF CIRCULAR CROSS SECTION

$$\tau_{max} = K\frac{16}{\pi d^3}PR \qquad \sigma_{max} = K\sigma\frac{32}{\pi d^3}PR$$

Author	Stress factors
A. Röver[3]	$K = \left[\frac{c}{c-\cos^2\alpha} + \frac{1+\sin^2\alpha}{4c}\right]\cos\alpha$ $K\sigma = \left[\frac{c}{c-\cos^2\alpha} + \frac{\sin^2\alpha}{4c}\right]\sin\alpha$
E. Honegger[5]	$K = \left[\cos\alpha\frac{\sqrt{c^2-1}}{c-\cos^2\alpha}\right]\left[\frac{1}{1+\frac{1}{6c^2}+\frac{1}{16c^4}}\right] + \left[\frac{0.616}{c}\cos\alpha\right]$ $K\sigma = \left[\frac{1}{4}\sin^2\alpha + \left(\frac{1}{1+\frac{1}{4c^2}+\frac{5}{32c^4}}\right)\times\left(\frac{c}{c+\cos^2\alpha}\right)\right]\sin\alpha$
O. Göhner[6]	$K = \cos\alpha\left[\frac{\left(\frac{c}{c-\cos^2\alpha}+\frac{1}{4}\frac{\cos^2\alpha}{c}+\frac{1}{16}\frac{\cos^4\alpha}{c^2}\right)}{\left(c^2-\frac{13}{16}\cos^4\alpha\right)} + \frac{[0.62\cos^2\alpha(c-\cos^2\alpha)+0.53\cos^4\alpha]\tan^2\alpha}{c(c-\cos^2\alpha)}\right]$ $K\sigma = \sin\alpha\left[1+0.87\frac{\cos^2\alpha}{c}+\frac{0.64\cos^4\alpha}{c(c-\cos^2\alpha)}+\frac{1}{4c}\right]$
M. Bergsträsser[7]	$K = \left[\frac{c+0.50+\sin^2\alpha}{c-0.75+1.51\sin^2\alpha}\right]$

NOTE: The notes [3,5,6,7] after authors' names refer to previous footnotes in text.

TABLE 2 FORMULAS FOR MAXIMUM SHEAR STRESS FOR CLOSE-COILED SPRINGS OF CIRCULAR CROSS SECTION FOR $\alpha = 0$

$$\tau_{max} = K_0\frac{16}{\pi d^3}PR$$

Author	Maximum-shear-stress factor K_0 for $\alpha = 0$
A. Röver[3]	$\frac{c}{c-1} + \frac{1}{4c}$
A. M. Wahl[4]	$\frac{4c-1}{4c-4} + \frac{0.615}{c}$
E. Honegger[5]	$\sqrt{\left(\frac{c+1}{c-1}\right)}\times\frac{1}{\left[1+\frac{1}{6c^2}+\frac{1}{16c^4}\right]} + \frac{0.616}{c}$
O. Göhner[6]	$\left[\frac{c}{c-1}+\frac{1}{4c}+\frac{1}{16c^2}\right]\times\left[\frac{c^2-1}{c^2-0.8125}\right]$
M. Bergsträsser[7]	$\frac{c+0.5}{c-0.75}$

τ_{max} = maximum shear stress
K_0 = maximum-shear-stress factor for $\alpha = 0$
d = diameter of wire
P = load
R = mean radius of spring
α = pitch angle of spring
c = $2R/d$

for the maximum-shear- and bending-stress factors by the five authors are briefly summarized in Table 2 for a pitch angle α, and the maximum-shear-stress factors for a pitch angle equal to zero in Table 2, the bending stress being zero for this particular case. We find that Röver's formulas for the stress factor for α equals zero are even simpler than Wahl's. Honegger's formulas give an additional correction factor for the movement of the center of the cross section of the wire due to axial loading. Göhner's formulas are more complicated than any of the others. However, Bergsträsser reduces Göhner's formulas to a simplified form. The difference of both these values for the various values of c is so small that it is only at the third decimal that a mathematical discrepancy is noticed.

The percentage difference in the maximum-shear-stress factors relative to Röver's values are shown in Fig. 1. Here we find that Honegger gives the highest positive value, the maximum being 3.05 per cent for c equals 5.75; Wahl gives a maximum value of 0.8 per cent at c equals 6.0. The values by Göhner and Bergsträsser are below Röver's. The general conclusion to be deduced from this information is that the formulas presented by the five authors are practically identical, the differences being negligible.

It is worthy of note that this analysis entirely clarifies all doubtful points in the calculation of various stresses in springs. There is complete agreement in the various maximum-shear-stress factors published by these authors. Having dealt with the principal facts and formulas developed by Röver, Wahl, Honegger, Göhner, and Bergsträsser, we shall now compare the stress factors in relationship to the simple torsion theory derived from the formulas published by these authors. The relative comparison of Röver, Wahl, Honegger, and Göhner is represented in Fig. 2. This gives a realistic picture of the analysis. All these curves show a shear-stress factor for a pitch angle equal to zero plotted as a function of $\frac{R}{r}$. This shear-stress factor takes into consideration the torsion and the direct stress for a zero pitch angle with a bending stress equal to zero. The curves show distinctly that Röver's, Wahl's, and Göhner's values are very close to each other. We find that the curve based on Wahl's values is between the curves by Röver and Honegger for the values of c above 2.9. For values of c below 2.9, the Wahl curve is between the Göhner and Röver curves, the difference being extremely small.

The Honegger curve shows only a slight deviation from the others. It gives the lowest values for the shear-stress factor for

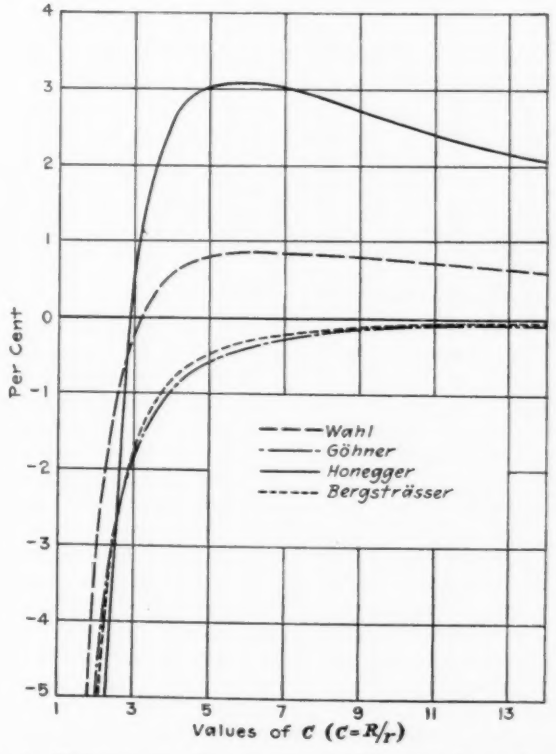

FIG. 1 PERCENTAGE DIFFERENCE IN MAXIMUM-SHEAR-STRESS FACTORS RELATIVE TO RÖVER'S VALUES

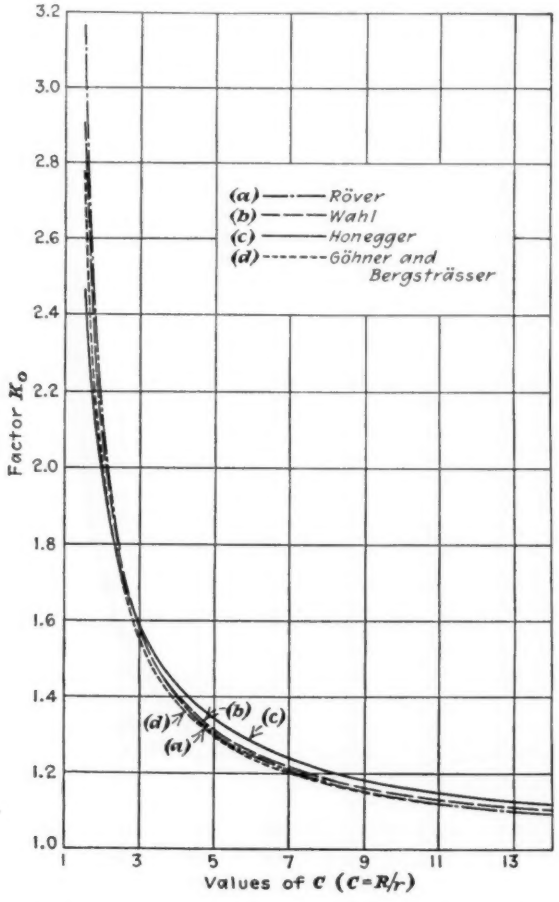

FIG. 2 MAXIMUM-SHEAR-STRESS FACTORS FOR HEAVY CLOSE-COILED HELICAL SPRINGS OF CIRCULAR CROSS SECTION

$$\left(\tau_{max} = K_0 \times \frac{16}{\pi d^3} PR\right)$$

c below 2.9 and the highest for c above 2.9. From an engineer's point of view the values of the five authors are practically equal.

Tests on Stresses in Springs. This intense survey would be incomplete without including some of the major tests carried out by various authorities. Credit is first due to Wahl for having carried out such tests for low values of c. His experiments were made on springs for a value of $c = 3.14$ and 2.98, respectively. He found that the stresses determined on tests agreed closely with his own formulas. Further elaborate tests were made by Honegger to check his own theory and formulas, and these springs had a value of $c = 3$ and 3.9. Also his test values agreed with his formulas. Now for the value of $c = 3$ the calculated stress factor for Wahl and Honegger is 1.580 and 1.592, respectively, the difference being only 0.76 per cent. More than twelve tests were made on a number of springs by Thiersch in 1934, having c values from 3.92 to 14.15. He states that when the test values are compared with the Göhner factors, the variation is +10.9 to —9.4 per cent. In this case the springs had only a wire diameter of 0.06 in. to 0.16 in., while all previous tests were carried out on actual springs.

Twenty-one fatigue tests on springs were made by Zimmerli on a large number of springs for $c = 3.5$ to 12 for a range of stress of 20,000 to 95,000 lb per sq in. He states that these confirm the Wahl stress factor.

As the calculated values of the four authors for the maximum shear stress on springs agree so well, one is not surprised to find that the tests carried out by the various experimenters are also in close agreement.

Conclusions. The object of this comprehensive survey has been to collate published information to enable one to form a definite opinion of the present-day knowledge of the theory and practice of helical springs of circular cross section. A serious attempt has been made to summarize the existing facts, to assist toward a better understanding of the principal theories and formulas, and to simplify the evaluation of the maximum stresses in springs. We obtain the very surprising result that the stress factors relative to the simple torsion theory for the five principal authors agree closely, the differences being very minute. Furthermore, this is confirmed by various authorities who have made tests on actual springs.

WM. HAESSLER.[8] The writer has on various occasions made fairly complete studies of railway-car spring suspensions, chiefly for the purposes of deriving the vibration characteristics.

It is his experience that, for the oscillating stress conditions existing in railway-truck helical springs, the use of the Wahl correction factor will yield a satisfactory spring from the standpoint of life.

It is well to note that the surfaces of helical railway springs are in general quite rough and this rough surface presents the problem of stress concentration in a region where the stresses are at their peak. This condition largely compensates for the overcorrection in using the Wahl factor, which is noticeable when smooth polished surfaces exist.

E. T. P. NEUBAUER.[9] During the discussion of Mr. Wahl's paper a question was brought up regarding the effect on allowable stresses, to which the writer answered: When springs are subjected to fairly wide variations of temperature, the minimum stress or initial stress is important in order to avoid having the spring take a set.

Fig. 3 illustrates this point. The spring subjected to the stresses of curve A took a set while the spring subjected to the stresses of curve B though a higher maximum stress, did not take a set. In both cases the running temperature of the springs was about 300 to 350 F. The maximum stress was applied for only short intervals.

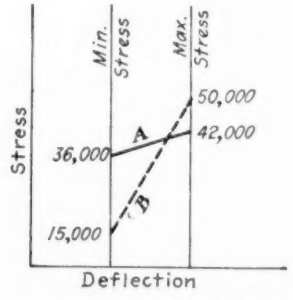

FIG. 3 DIAGRAM OF STRESS APPLICATIONS

AUTHOR'S CLOSURE

The author wishes to thank Mr. Finniecome for his thorough and comprehensive analysis of the results obtained by using spring formulas derived by various authorities. As mentioned by Mr. Finniecome, this analysis shows that the numerical differences between the results, as calculated by using the formulas given by Röver, Göhner, Honegger, Bergsträsser, or the author,

[8] American Car and Foundry Company, New York, N. Y. Mem. A.S.M.E.

[9] York, Pa.

are negligible from a practical standpoint. Since the author's formula is quite widely applied in this country and also agrees closely (within about 1½ per cent for practical springs) with Göhner's more exact equations, which were derived on the basis of the theory of elasticity, it was used in carrying out the analysis given in the present paper. Practically the same results would have been obtained if the formulas given by the other authorities mentioned had been employed.

It should be noted that the primary purpose of the paper was to evaluate in a rational way the effect of wire or bar curvature on the allowable stress in springs under repeated or fatigue loading, and to explain why higher stresses (figured by using the K-factor, Fig. 1 of the paper) are obtained for the springs of smaller index. A discussion of the effects of permanent set under static load and of creep under temperature, although admittedly of much importance to spring designers, is considered to be beyond the scope of the present paper. However, assuming that stress-concentration effects due to curvature may be neglected in figuring stresses due to static loads, then, for a spring subject to a static load, it follows that the stress as obtained by using the K-factor should be divided by K_e (Fig. 1 of the paper) to obtain a comparative stress value for design purposes. It is the author's opinion that, for most spring materials which have some ductility or elongation, this procedure is logical and the resulting value of stress will probably be a closer measure of the tendency of the spring to creep or take a set under static loads than would the peak-stress value obtained by using the K-factor. For extremely brittle materials, this procedure is open to question and should not be used. In the author's opinion there is a definite need for more test data on the creep or settage of springs under constant load at high stress both at normal and elevated temperatures. Although the tests, carried out under the auspices of the Special Research Committee on Mechanical Springs, have constituted a good start in this direction, in addition there exists a definite need for more fatigue-test data on springs of different indexes and materials, and under various loading conditions.

Book Reviews

Mathematics

THE GEOMETRY OF DETERMINENTAL LOCI. By T. G. Room, Professor of Mathematics in the University of Sydney. The University Press, Cambridge. The Macmillan Company, New York, 1939. Cloth, 7¼ × 10½ in., xvi and 483 pp., $10.

REVIEWED BY R. M. THRALL[1]

THIS book is written for the pure mathematician, and it is the reviewer's opinion that it contains very little material of use in applied mathematics, except, perhaps, in problems whose solution requires study of linear equations in which the coefficients are linear functions of several parameters. The language and setting of the treatise are those of projective and algebraic geometry. The loci discussed are also of importance in many fields of algebra, including trilinear form classification, group theory, and linear algebras.

The possible use of this theory in applied mathematics can be seen from the following discussion. The necessary and sufficient condition that the set of q linear homogeneous equations A: $\sum_{j=1}^{p} x_{ij}y_j = 0$, $i = 1, \ldots, q$ shall have a nontrivial solution (i.e. one different from $y_1 = \ldots = y_p = 0$) is that the coefficient matrix (x_{ij}) shall be of rank $p - 1$ or less. In the most elementary case the coefficients x_{ij} are given constants. However, in many cases the x_{ij} are of the form $a_{ij} + xb_{ij}$, where a_{ij} and b_{ij} are constants and x is a parameter. (For instance, vibration problems, where x represents the square of the natural frequencies.) If we set $x = x_1/x_0$ and multiply through by x_0 in each equation we get an equivalent system of equations whose coefficients are linear homogeneous functions of two parameters, x_0 and x_1. If, now, $p = q$ the condition for a nontrivial solution of the equations A is that the determinant $f(x_0, x_1) = |x_{ij}|$ shall vanish, and thus many important properties of the equations A are reflected in the determinental locus $f(x_0, x_1) = 0$.

More generally if $x_{ij} = \sum_{h=0}^{n} a_{hij}x_h$ for any n, p, q the values of $x_0, \ldots, x_n$ for which (x_{ij}) is of rank r constitute a *determinental locus*, V^r, in a projective space of n dimensions. The theory of invariant factors (or elementary divisors) suffices for $n = 1$, so that applications of this work begin with $n = 2$, or with problems whose related equations A involve two or more parameters.

The first chapter explains the notation and gives the projective background and definitions. The next six chapters are concerned with properties of the most general manifolds V^r. The remaining nine chapters are devoted to detailed study of special manifolds V^r (i.e., small values of n, p, q or with specially defined coefficients).

Modern Developments in Fluid Dynamics

MODERN DEVELOPMENTS IN FLUID DYNAMICS. Vols. I and II. By the Fluid Motion Panel of the Aeronautical Research Committee and others, edited by S. Goldstein. Clarendon Press, Oxford, 1938. 6 × 9¼ in. Vol. I, xxii and 330 pages, 91 figs., 29 plates. Vol. II, xi and 372 pages, 165 figs., 5 plates, 50 s.

REVIEWED BY HUGH L. DRYDEN[2]

WITH secondary title, "An Account of Theory and Experiment Relating to Boundary Layers, Turbulent Motion, and Wakes," these two volumes by a galaxy of distinguished British scientists bring to student, research worker, and practicing engineer a connected account of practically all of the recent developments, both theoretical and experimental, in the aforementioned fields, which have hitherto been available only in scattered papers. As such, it is one of the indispensable books. It is a tribute to the rapid development of fluid mechanics that such a book could be written so shortly after the appearance of the six volumes of Aerodynamic Theory edited by Dr. William F. Durand with so little duplication of subject matter.

The volumes were written at the instigation of the late Sir Horace Lamb and it was hoped that they would appear under his editorship, but Providence decreed otherwise. They are sponsored by the Aeronautical Research Committee of Great Britain and dedicated to Lamb. The actual writing was done

[2] Chief, Mechanics and Sound Division, National Bureau of Standards, Washington, D. C. Mem. A.S.M.E.

by members of the Fluid Motion Panel, L. Bairstow, A. Fage, S. Goldstein, B. M. Jones, A. R. Low, E. Ower, E. F. Relf, L. F. G. Simmons, R. V. Southwell, H. B. Squire, and G. I. Taylor, with the collaboration of Messrs. V. M. Falkner, L. Howarth, L. Rosenhead, and H. C. H. Townend. There is no indication of the authorship of the several sections. So skillfully has the editor, Dr. Goldstein, woven the separate contributions into a continuous fabric, that there are no observable differences in style or quality of treatment.

The subject matter is restricted to rational analysis and experiments of interest in guiding the analysis and checking its validity. After two chapters of an introductory nature giving a general discussion of real and ideal fluids and boundary-layer theory, the equations of viscous fluid flow are developed, followed by the mathematical theory of motion in a boundary layer. The discussion of boundary-layer theory is very complete, including the simple methods of low degree of approximation as well as the relatively more exact methods. The available comparisons with experiment are critically discussed.

A chapter on turbulence, probably written by G. I. Taylor, gives a compact account of the theory of turbulence, including Taylor's important contributions to the theory of isotropic turbulence. This chapter is followed by a brief survey of experimental apparatus and methods of measurement.

Seven chapters deal with general flow phenomena, classified according to boundary conditions. The discussion of pipes, channels, and flat plates together in two chapters aids greatly in bringing out the correspondence in behavior. Laminar flow, transition from laminar to turbulent flow, and turbulent flow are discussed in turn. The next five chapters deal with flow around symmetrical cylinders (drag), flow past asymmetrical cylinders (airfoils, lift), flow past solid bodies of revolution (spheres and airship shapes), boundary-layer control, and wakes.

Two final chapters give an account of heat transfer in laminar and turbulent flow.

Extensive footnotes and summaries at the ends of chapters were inserted at a late stage in the printing to include the very latest work. These added references are to papers appearing in 1937 and early in 1938.

The emphasis is naturally on experiments pertaining to aerodynamics, but everyone interested in fluid mechanics will desire to have these two volumes at hand.

Physics

PROCEDURES IN EXPERIMENTAL PHYSICS. By John Strong, Ph.D., in collaboration with H. Victor Neher, Ph.D., Albert E. Whitford, Ph.D., C. Hawley Cartwright, Ph.D., and Roger Hayward. (Prentice-Hall Physics Series, E. U. Condon, Ph.D., editor.) Prentice-Hall, Inc., New York, 1938. Cloth, 6 × 9¼ in., x and 642 pp., illustrated, $5.

REVIEWED BY FRANCIS BITTER[3]

THIS is an exceedingly good book concerned primarily with the technique of physical experimentation. Although some of the material covered may be found in handbooks and textbooks, most of it is of a sort that is generally acquired by experience only, the sort of thing that may be referred to as "general knowledge" by those familiar with "the art." A feature of the book is the large number of illustrations which help enormously in making the text clear with a minimum of effort on the part of the reader.

The subjects covered include chapters on glass blowing, laboratory optical work, electrometers and electroscopes, Geiger counters, vacuum thermopiles, photoelectric cells and amplifiers, and one on light sources, filters, and optical instruments. These will perhaps be of less interest to engineers and metallurgists than the sections of the book devoted to high vacuum, evaporation and sputtering, the use of fused silica, photography in the laboratory, heat and high temperature, notes on the materials of research, notes on the construction and design of instruments and apparatus, and on molding and casting. Experimenters generally should find it desirable to keep this book on their desks for reference, and to browse in it occasionally for inspiration.

Mathematics

ELEMENTARY MATRICES. By R. A. Frazer, W. J. Duncan, and A. R. Collar. The University Press, Cambridge, The Macmillan Company, New York, 1939. Cloth, 6 × 10 in., xiii and 416 pp., figs., $8.50.

REVIEWED BY LOUIS A. PIPES[4]

THE authors of this book have by means of their investigations for the Aeronautical Research Committee demonstrated the great utility of the application of matrix algebra to classical mechanics. This is the first book that has appeared which develops the subject from its foundations and illustrates the application of matrix algebra to ordinary linear differential equations with constant and variable coefficients and to classical mechanics.

The first four chapters are devoted to the development of matrix algebra and the differential and integral calculus of matrixes without specific applications to problems of dynamics. The nonmathematical reader whose principal interest is mechanics may find the perusal of these chapters somewhat tedious because of the lack of illustrative material to subjects of his special interest. Having developed the necessary theorems, the authors devote chapters 5 and 6 to an excellent detailed exposition of linear ordinary differential equations from the matrix point of view.

Chapter 7 illustrates the use of matrix algebra in the numerical solution of systems of linear differential equations with variable coefficients. The last six chapters contain a very clear exposition of those phases of mechanics of particular importance to the theory of oscillations of aeronautical structures. Powerful iterative methods for the numerical solution of complex oscillatory systems are introduced with actual physical examples such as torsional oscillations of a multicylinder engine, flexural oscillations of a tapered beam, etc. Chapter 11 is devoted to dynamical systems with solid friction and the book is concluded with illustrative applications of friction theory to flutter problems.

This book affords an excellent introduction to the application of matrix algebra to the treatment of linear dynamical systems and although the illustrative examples are chosen from the realm of mechanics, the theory could equally well be applied to electrical systems. The only criticism that might be offered is that the long mathematical preliminary of the first four chapters would have been made more palatable to the nonmathematical reader with strong interests in mechanics by the earlier introduction of illustrative material from this field. However, the procedure followed by the authors is more logical and the reader who masters these chapters is later richly rewarded for his efforts.

Foreword

THE Transactions of The American Society of Mechanical Engineers include selected technical papers and reports delivered at meetings of the Society, its Professional Divisions, and its Local Sections, the *Journal of Applied Mechanics* (contributions of the Applied Mechanics Division), certain records of the Society of permanent value, and indexes to its publications.

In order to secure the advantages of timeliness and greater usefulness in issuing these Society Records, the material comprising them is divided into a number of parts, each one of which is mailed as a supplement to one of the regular monthly issues of the Transactions. For 1939, the first of these, the present issue, contains the personnel of the Council and committees for the year. Another, to be issued sometime later in the year, will contain memorial notices of deceased members. The indexes to miscellaneous publications, *Mechanical Engineering*, and to the Transactions themselves, must, necessarily, be issued in 1940, and will probably be mailed as a supplement to the January issue of that year.

In binding the 1939 Transactions, all of these parts of the Society Records will be assembled at the back of the volume as has been customary for several years. To aid in locating references in the bound volumes, the page numbers of the sections containing the *Journal of Applied Mechanics* and the Society Records are preceded by the letters A and RI, respectively.

THE COMMITTEE ON PUBLICATIONS

Bachrach

ALEXANDER G. CHRISTIE

PRESIDENT OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS
1938–1939

Alexander Graham Christie

ALEXANDER GRAHAM CHRISTIE, president of The American Society of Mechanical Engineers for the year 1938–1939, is professor of mechanical engineering at Johns Hopkins University, Baltimore, Md., but is more widely known throughout the world for his work in the design of power plants. He was born in Manchester, Ont., Canada, in 1880, and was graduated from the School of Practical Science, University of Toronto, in 1901 and received his M.E. degree from the same school in 1913.

Upon his graduation in 1901, Professor Christie started his engineering career as a mechanic in the East Pittsburgh, Pa., plant of the Westinghouse Machine Company, working his way up to the positions of erecting and test engineer and foreman, where he was able to do his part in the early development and construction of steam turbines and gas engines. After being in charge of the Westinghouse turbine and gas-engine exhibits at the World's Fair in St. Louis, Mo., in 1904, he resigned to become an instructor in mechanical engineering at Cornell University. However, he resigned again the following year in order to take charge of the erection, test, and operation of the first steam turbines built by the Allis-Chalmers Company, where he also did work on condensers, steam engines, gas engines, and pumps. In the fall of 1907, he became mechanical engineer in charge of construction and operation of the power plant of Western Canada Cement & Coal Company, Exshaw, Alberta, Canada.

But with his considerable experience in the design and construction of power-plant equipment and machinery, it was not long, 1909 to be exact, before Professor Christie was invited to become assistant professor of steam and gas engineering at the University of Wisconsin and later associate professor. In 1914, he joined the faculty of Johns Hopkins University as associate professor of mechanical engineering, being promoted in 1920 to a full professorship. Since 1916, he has been in charge of the evening engineering and technological school of the University.

In his connections with various engineering and manufacturing firms both here and abroad, he has worked on the design and construction of such power plants as Cahokia, Lake Shore, and Avon Beach in Cleveland, Gould Street in Baltimore, Md., India Basin in San Francisco, Three Rivers in Quebec, Edmonton, Alberta, Can., Salt Creek in Wyoming, and also on power projects in Great Britain, Germany, Sweden, Switzerland, France, Denmark, Perak, Asia, Queensland, Australia, and Argentina, S.A. At the present time, he is consulting engineer to several concerns on designs of a new superimposed power plant and of industrial plants.

Elected to membership in the A.S.M.E. in 1907, Professor Christie served as secretary-treasurer of the Baltimore Section for many years. Since 1918, he has been a member of various committees on Power Test Codes, being today vice-chairman of the Standing Committee on Power Test Codes. He has also given freely of his valuable time to the Society by serving on the Society's Committee on Publications, Nominating Committee, and Professional Conduct Committee; and as manager for the years 1922 to 1925 and as vice-president from 1925 to 1927.

From 1919 to 1922, Professor Christie was chairman of the Joint Committee on Code of Ethics of all the national engineering societies. He is a member of the Engineers' Club of Baltimore as well as that of New York. In the last few years, Professor Christie has been or still is a member of the division of engineering, National Research Council; Prime Movers Committee, Edison Electric Institute; American Advisory Committee, International Electrotechnical Commission; and the World Power Conference.

As an authority on steam turbines and power-plant equipment, Professor Christie has written many articles for technical journals, here and abroad. He is the author of the steam-turbine section of both Sterlings' "Marine Engineer's Handbook" and Kent's "Mechanical Engineer's Handbook."

The American Society of Mechanical Engineers

HEADQUARTERS: 29 West 39th St., New York, N.Y.
MID-WEST OFFICE: Room 1617, 205 West Wacker Drive, Chicago, Ill.
MID-CONTINENT OFFICE: 211 Midco Building, Tulsa, Okla.

THE members of the Council and of its standing and special committees given on the following pages are those in office on January 1, 1939, serving for the official year 1938–1939. The terms of office of members of other committees are not fixed by the official calendar.

Officers and Council

PRESIDENT

Alexander G. Christie

PAST-PRESIDENTS

Terms expire December

A. A. Potter (1939)
Ralph E. Flanders (1940)
William L. Batt (1941)
James H. Herron (1942)
Harvey N. Davis (1943)

VICE-PRESIDENTS

Terms expire December, 1939

Harte Cooke
Warren H. McBryde
Henry H. Snelling
L. W. Wallace

Terms expire December, 1940

W. Lyle Dudley
Alfred Iddles
James W. Parker

MANAGERS

Terms expire December, 1939

Edward W. Burbank
Kenneth H. Condit
Samuel W. Dudley

Terms expire December, 1940

Carl L. Bausch
Samuel B. Earle
Frank H. Prouty

Terms expire December, 1941

Clarke Freeman
William H. Winterrowd
Willis R. Woolrich

TREASURER

W. D. Ennis

SECRETARY

C. E. Davies

Chairmen of Standing Committees

Representatives on Council without vote

Finance, K. M. Irwin
Meetings and Program, R. F. Gagg

COMMITTEE TO COOPERATE WITH CONSUMER'S COUNCIL WITH RELATION TO ACTIVITIES OF NATIONAL BITUMINOUS COAL COMMISSION

K. M. IRWIN, *Chairman* — T. A. MARSH, *Secretary*

SUBCOMMITTEE ON MODEL SMOKE LAW

W. G. CHRISTY, *Chairman*

JOINT A.I.M.E. AND A.S.M.E. COMMITTEE ON FUEL VALUES

G. B. GOULD (A.I.M.E. Representative), *Chairman*

A.S.M.E. Representatives

A. D. BAILEY
E. H. BARRY
F. M. GIBSON
H. DRAKE HARKINS
J. C. HOBBS
A. L. PENNIMAN, JR.
E. B. RICKETTS
E. H. TENNEY

Graphic Arts Division

Formerly Printing Industries Division. Organized, 1922

B. D. STEVENS, *Chairman*

EXECUTIVE COMMITTEE

B. D. STEVENS, *Chairman*
T. E. DALTON, *Secretary*
A. E. GIEGENGACK
F. W. HOCH
W. B. LAUGHTON
R. G. MACDONALD
W. M. PASSANO
B. L. SITES
B. L. WEHMHOFF

Associates

G. H. CARTER
EDWARD EPSTEAN
W. C. GLASS
W. C. HUEBNER
W. R. MAULL

SUBCOMMITTEE FOR GRAPHIC ARTS FORUM

F. W. HOCH, *Chairman*
T. E. DALTON
R. G. MACDONALD

Heat Transfer Professional Group

Organized, 1938

T. B. DREW, *Chairman*

EXECUTIVE COMMITTEE

T. B. DREW, *Chairman*
E. D. GRIMISON, *Group Secretary*
H. C. HOTTEL
W. S. PATTERSON
A. K. SCOTT

Advisory Associates

C. E. LUCKE
J. H. SENGSTAKEN

COMMITTEE ON COORDINATION

E. D. GRIMISON, *Chairman*

Divisional Representatives

Fuels, B. J. CROSS
Iron and Steel, W. TRINKS
Oil and Gas Power, F. G. HECHLER
Petroleum, T. D. TIFFT
Power, G. A. GAFFERT
Process Industries, A. WEISSELBERG

Liaison Officer for Local Section

A. K. SCOTT

Members at Large

L. M. K. BOELTER
R. H. HEILMAN
R. H. NORRIS
G. L. TUVE

COMMITTEE ON PAPERS

W. S. PATTERSON, *Chairman*
R. A. BOWMAN
W. L. DE BAUFRE
E. D. GRIMISON
R. A. SHERMAN

COMMITTEE ON TESTING TECHNIQUE

B. J. CROSS
H. C. HOTTEL
A. K. SCOTT

Hydraulic Division

Organized, 1926

FORREST NAGLER, *Chairman*

EXECUTIVE COMMITTEE

FORREST NAGLER, *Chairman*
F. G. SWITZER, *Vice-Chairman*
L. J. HOOPER, *Secretary*
S. LOGAN KERR
M. P. O'BRIEN
E. B. STROWGER

COMMITTEE ON WATER HAMMER

Honorary Chairman, LORENZO ALLIEVI, Rome, Italy

S. LOGAN KERR, *Sponsor and Chairman*

N. R. GIBSON
EUGENE HALMOS
L. F. MOODY
R. S. QUICK
E. B. STROWGER

Affiliated Societies and Their Representatives:

American Society of Civil Engineers, N. R. GIBSON and FORD KURTZ
American Water Works Association, F. M. DAWSON and L. H. KESSLER

Associate Members, Representing:

Australia, GEORGE HIGGINS
Brazil, A. W. K. BILLINGS and F. KNAPP
Engineering Institute of Canada, R. W. ANGUS and F. M. WOOD
France, LOUIS BERGERON and CHARLES CAMICHEL
Germany and Verein deutscher Ingenieure, D. THOMA
Great Britain and Institution of Mechanical Engineers, E. BRUCE BALL and A. H. GIBSON
Italy, GAETANO FANTOLI and ALBINO PASINI
Switzerland, CHARLES JAEGER and O. SCHNYDER

COMMITTEE ON CAVITATION

E. B. STROWGER, *Sponsor*
L. F. MOODY, *Chairman*

COMMITTEE ON GENERAL HYDRAULICS

M. P. O'BRIEN, *Sponsor*

COMMITTEE ON HYDRAULIC PRIME MOVERS

FORREST NAGLER, *Sponsor*
J. FRANK ROBERTS, *Chairman*

COMMITTEE ON PUMPING MACHINERY

F. G. SWITZER, *Sponsor*
R. L. DAUGHERTY, *Chairman*

Iron and Steel Division

Organized, 1927

T. H. WICKENDEN, *Chairman*

EXECUTIVE COMMITTEE

T. H. WICKENDEN, *Chairman*
MORRIS STONE, *Secretary*
J. A. CLAUSS
G. L. FISK
R. J. WEAN
S. M. WECKSTEIN

Associates

A. J. BOYNTON
J. H. HITCHCOCK
S. M. MARSHALL
J. H. ROMANN
G. T. SNYDER
W. TRINKS
W. R. WEBSTER

Machine Shop Practice Division

Organized, 1921

A. M. JOHNSON, *Chairman*

EXECUTIVE COMMITTEE

A. M. JOHNSON, *Chairman*
ERIK OBERG, *Secretary*
W. A. JOHNSON, *Staff Secretary*
WARNER SEELY
B. G. TANG
J. R. WEAVER

SUBCOMMITTEE ON FOUNDRY PRACTICE

JAMES THOMSON, *Chairman*
R. E. KENNEDY, *Secretary*

SUBCOMMITTEE ON MACHINE DESIGN

E. S. AULT, *Chairman*
A. E. R. DE JONGE
J. MARIN

SUBCOMMITTEE ON LUBRICATION ENGINEERING

W. F. PARISH, *Chairman* C. M. LARSON
H. J. MASSON

SUBCOMMITTEE ON CUTTING METALS

HANS ERNST, *Chairman*

(See also Special Research Committee on Cutting of Metals, page RI-24)

SUBCOMMITTEE ON WELDING

C. W. OBERT, *Chairman*

Management Division

Organized, 1920

W. H. KUSHNICK, *Chairman*

EXECUTIVE COMMITTEE

W. H. KUSHNICK, *Chairman* HAROLD B. BERGEN
L. N. ROWLEY, JR., *Secretary* J. A. JACOBS
J. R. BANGS L. C. MORROW

Associates

C. W. LYTLE F. E. RAYMOND
J. A. PIACITELLI J. R. SHEA

DEPRECIATION STUDIES

P. T. NORTON, JR. H. V. COES

Materials Handling Division

Organized, 1920

R. B. RENNER, *Chairman*

EXECUTIVE COMMITTEE

R. B. RENNER, *Chairman* C. F. DIETZ
F. J. SHEPARD, JR., *Secretary* J. A. JACKSON
G. E. HAGEMANN, *Vice-Chairman* M. C. MAXWELL

Associates

NIXON ELMER F. E. MOORE
R. H. MCLAIN E. D. SMITH
J. B. WEBB

Oil and Gas Power Division

Organized, 1921

L. H. MORRISON, *Chairman*

EXECUTIVE COMMITTEE

L. H. MORRISON, *Chairman* F. G. HECHLER
M. J. REED, *Secretary* C. W. GOOD
CARL BEHN E. J. KATES

Associates

HARTE COOKE ERNEST NIBBS
H. E. DEGLER LEE SCHNEITTER
L. R. FORD C. G. A. ROSEN

SUBCOMMITTEE ON OIL ENGINE POWER COST REPORT FOR 1938

H. C. MAJOR, *Chairman* M. J. REED, *Secretary*

SUBCOMMITTEE ON PAPERS AND PROGRAM

LEE SCHNEITTER, *Chairman* O. H. ALLEN
C. W. GOOD

SUBCOMMITTEE ON EDITING PAPERS SUBMITTED

E. J. KATES ERNEST NIBBS

Petroleum Division

Organized, 1925

Reorganized, 1937

C. J. COBERLY, *Chairman*

EXECUTIVE COMMITTEE

C. J. COBERLY, *Chairman*
J. H. ENGELBRECHT, *Staff Secretary*
T. D. TIFFT, *1st Vice-Chairman*
W. F. HERBERT, *2nd Vice-Chairman*
H. L. EGGLESTON, *3rd Vice-Chairman*
GLENVER MCCONNELL, *4th Vice-Chairman*

GENERAL COMMITTEE

Atlantic	*Mid-Continent*	*Pacific*
E. H. BARLOW	W. H. CARSON	C. J. COBERLY
A. H. MILLER	W. F. HERBERT	H. L. EGGLESTON
V. W. SMITH	GLENVER MCCONNELL	R. J. REED
C. E. SPERRY		L. G. METCALF
T. D. TIFFT		C. C. SCHARPENBERG

Power Division

Organized, 1920

G. A. GAFFERT, *Chairman*

EXECUTIVE COMMITTEE

G. A. GAFFERT, *Chairman* W. A. CARTER
O. F. CAMPBELL, *Secretary* G. C. EATON
E. L. HOPPING

Process Industries Division

Organized, 1934

J. H. SENGSTAKEN, *Chairman*

EXECUTIVE COMMITTEE

J. H. SENGSTAKEN, *Chairman* R. F. O'MARA
T. R. OLIVE, *Secretary* A. F. SPITZGLASS
THEODORE BAUMEISTER, JR. ARNOLD WEISSELBERG
C. E. HARRINGTON VICTOR WICHUM
J. W. HUNTER W. R. WOOLRICH
J. A. MCPHERSON F. L. YERZLEY

COMMITTEE ON INDUSTRIAL INSTRUMENTS AND REGULATORS

EXECUTIVE COMMITTEE

E. S. SMITH, *Chairman* A. F. SPITZGLASS, *Secretary*
E. D. HAIGLER, *Vice-Chairman*
E. S. LEE, *Chairman*, Bibliography Committee
P. G. EXLINE, *Chairman*, Pressure and Temperature Committee
J. J. GREBE, *Chairman*, Program Committee
A. F. SPITZGLASS, *Chairman*, Quantitative Analysis Committee
J. I. YELLOTT, *Chairman*, Terminology Committee
M. J. ZUCROW, *Chairman*, Translation Committee

COMMITTEE ON AIR CONDITIONING

C. F. KAYAN, *Chairman*

COMMITTEE ON DRYING

ARNOLD WEISSELBERG, *Chairman*

COMMITTEE ON FANS AND BLOWERS

THEODORE BAUMEISTER, JR., *Chairman*

COMMITTEE ON FOOD PROCESSING

G. L. MONTGOMERY, *Chairman*

COMMITTEE ON MECHANICAL SEPARATION

R. F. O'Mara, *Chairman*

COMMITTEE ON PAPER AWARDS AND HONORS

C. E. Lucke, *Chairman*

COMMITTEE ON PROGRAM

J. W. Hunter, *Chairman*

COMMITTEE ON PULP AND PAPER

J. A. McPherson, *Chairman*

COMMITTEE ON RUBBER AND PLASTICS

F. L. Yerzley, *Chairman*

COMMITTEE ON SANITATION

William Raisch, *Chairman*

COMMITTEE ON SUGAR

F. M. Gibson, *Chairman*

COMMITTEE ON SULPHUR

B. E. Short, *Chairman*

COMMITTEE ON VEGETABLE OILS

W. R. Woolrich, *Chairman*

Railroad Division

Organized, 1920

C. T. Ripley, *Chairman*

EXECUTIVE COMMITTEE

C. T. Ripley, *Chairman*
M. B. Richardson, *Secretary*
L. H. Fry (1940)
A. I. Lipetz (1941)
D. S. Ellis (1942)
J. R. Jackson (1943)

GENERAL COMMITTEE (RR2)

C. T. Ripley, *Chairman*
J. G. Adair (1939)
F. E. Russell (1939)
R. W. Salisbury (1939)
O. C. Cromwell (1940)
W. E. Dunham (1940)
H. C. Wilcox (1940)
A. Giesl-Gieslingen (1941)
K. F. Nystrom (1941)
L. W. Wallace (1941)
E. G. Young (1941)
R. S. Binkerd (1942)
F. E. Lyford (1942)
F. G. Lister (1943)
John Roberts (1943)
G. A. Young (1943)

PAST-CHAIRMEN (RR3)

James Partington (1923–1924)
C. E. Chambers (1925)
H. B. Oatley (1926–1927)
Wm. Elmer (1928)
R. S. McConnell (1929)
A. F. Stuebing (1930)
Eliot Sumner (1931)
T. C. McBride (1932)
L. K. Sillcox (1933)
C. B. Peck (1934)
C. E. Barba (1935)
Geo. W. Rink (1936)
W. H. Winterrowd (1937)
E. C. Schmidt (1938)

COMMITTEE ON MEETINGS AND PAPERS (RR5)

Lawford H. Fry, *Chairman* Harold C. Wilcox, *Vice-Chairman*

COMMITTEE ON REVIEW AND EDITING (RR5A)

H. B. Oatley
F. E. Lyford
James Partington
W. E. Woodard

COMMITTEE ON SURVEY (RR6)

E. G. Young, *Chairman*
B. S. Cain (Electrical Developments)
A. Giesl-Gieslingen (Foreign Developments)
K. F. Nystrom (Cars)
John Roberts (Canadian Developments)

COMMITTEE ON MEMBERSHIP (RR8)

T. C. McBride, *Chairman*
H. B. Oatley
M. B. Richardson
W. C. Sanders
W. M. Sheehan
L. K. Sillcox
A. G. Trumbull
H. C. Wilcox

Textile Division

Organized, 1921

J. D. Robertson, *Chairman*

EXECUTIVE COMMITTEE

J. D. Robertson, *Chairman*
R. DeVere Hope, *Secretary*
Wendell Brown
H. H. Iler
Albert Palmer
Earle Stall

Associates

A. W. Benoit
Winn Chase
W. L. Conrad
H. D. Learnard

J. J. McElroy

M. A. Golrick, Jr., *Metropolitan Representative*

Wood Industries Division

Organized, 1921

R. H. McCarthy, *Chairman*

EXECUTIVE COMMITTEE

R. H. McCarthy, *Chairman*
P. T. Norton, Jr., *Secretary*
T. D. Perry
A. W. Keuffel
C. B. Norris

Associates

C. L. Babcock
P. H. Bilhuber
H. B. Carpenter
F. P. Cartwright
G. E. French
A. S. Kurkjian
J. S. Mathewson
A. D. Smith, Jr.

MACHINING OF WOOD COMMITTEE

G. E. French, *Chairman*
C. L. Babcock
E. M. Davis
W. Kynoch
R. H. McCarthy
C. M. Thompson

Local Sections

ARTICLE B6A, PAR. 17: The Standing Committee on Local Sections shall, under the direction of the Council, have supervision of the Local Sections of the Society.

STANDING COMMITTEE

D. B. PRENTICE, *Chairman and Representative on the Council* (1939)
A. J. KERR (1940) J. N. LANDIS (1942)
H. L. EGGLESTON (1941) J. P. FERRIS (1943)

Junior Advisers

W. F. CARHART (1939) J. R. CAVE, JR. (1940)

Regional Group Delegates to Annual Conferences

Terms expire October, 1939

P. B. EATON, *Speaker for 1938 Conference*, Group III
C. A. HESCHELES, *Secretary*, Group II
C. P. HOWARD, Group I W. E. MCDOWELL, Group IV
J. M. DRISCOLL, Group II E. R. MCCARTHY, Group V
D. K. HUTCHCRAFT, Group VI

Terms expire October, 1940

S. F. DUNCAN, *Speaker for 1939 Conference*, Group VII
R. A. SPENCE, *Secretary*, Group I
C. A. HESCHELES, Group II N. C. EBAUGH, Group IV
J. T. REA, Group III C. J. FREUND, Group V
R. E. TURNER, Group VI

AKRON-CANTON

Organized: 1920
Territory: Counties of Richland, Ashland, Medina, Summit, Portage, Wayne, Stark, Holmes, Tuscarawas, Carroll, and Coshocton in Ohio
Number of Members: 129

EXECUTIVE COMMITTEE

JAMES FORREST, *Chairman* S. H. HAHN
M. R. BOWERMAN, *Vice-Chairman* G. J. SCHOESSOW
A. D. MACLACHLAN, *Secretary-Treasurer* A. W. SEEKINS
O. BIESHELT A. E. SHETLER
V. R. CAMP O. W. TRAUT
A. W. WALKER

ANTHRACITE-LEHIGH VALLEY

Organized: 1920, as Lehigh Valley; reorganized, 1928, as Anthracite-Lehigh Valley
Territory: Counties of Bradford, Susquehanna, Wayne, Sullivan, Wyoming, Lackawanna, Columbia, Luzerne, Monroe, Pike, Schuylkill, Carbon, Berks, Lehigh, Northampton in Pennsylvania, and Warren in New Jersey
Place of Meeting: One meeting annually at Allentown, Bethlehem, Easton, Hazleton, Pottsville, Reading, Scranton, and Wilkes-Barre
Local Organization: The Engineers' Club of Lehigh Valley
Number of Members: 192

EXECUTIVE COMMITTEE

F. C. PETERS, *Chairman* B. H. JENNINGS
C. W. BELL, *Vice-Chairman* J. B. LAUDIG
P. B. EATON, *Vice-Chairman* R. E. MOYER, JR.
J. T. REA, *Vice-Chairman* W. P. SAUNIER
C. M. MERRICK, 3D, *Secretary* E. A. SCHMIDT
M. C. STUART, *Treasurer* W. T. SOULIS
W. W. HAGERTY S. V. WOOD

ATLANTA

Organized: 1913
Territory: Radius of sixty miles from Atlanta, Ga.
Place of Meeting: Atlanta Athletic Club
Luncheon meeting every Monday at 12:30 p.m. at Atlanta Athletic Club
Number of Members: 83

ATLANTA (*continued*)

EXECUTIVE COMMITTEE

T. E. BELL, *Chairman* E. P. KRAMER
M. F. MERL, *Vice-Chairman* H. M. LANGE
E. A. HARPER, *Secretary-Treasurer* J. M. RITTELMEYER
R. A. TROTTER

BALTIMORE

Organized: 1916
Territory: Radius of thirty miles from Baltimore, Md.
Place of Meeting: Engineers Club of Baltimore
Luncheon meeting every Wednesday at 12:00 noon at Engineers Club
Number of Members: 171

EXECUTIVE COMMITTEE

C. R. CHISHOLM, *Chairman* K. P. HANSON
S. B. SEXTON, 3D, *Secretary-Treasurer* W. P. HILL
L. F. COFFIN G. W. KEEN
A. M. GOMPF P. J. KIEFER
Junior Group Chairman: J. H. BERRYMAN

BIRMINGHAM

Organized: 1915
Territory: Radius of sixty miles from Birmingham, Ala.
Place of Meeting: Tutwiler Hotel
Number of Members: 92

EXECUTIVE COMMITTEE

J. E. GETZEN, *Chairman* J. E. BUELL
R. A. POLGLAZE, *Vice-Chairman* G. R. OZLEY
W. J. MOORE, *Secretary-Treasurer*

BOSTON

Organized: 1909
Territory: Radius of thirty miles from Boston, Mass.
Place of Meeting: Rooms of the Engineering Societies of New England
Local Organization: Engineering Societies of New England
Number of Members: 537

EXECUTIVE COMMITTEE

JAMES HOLT, *Chairman* KERR ATKINSON
H. K. DEAN, *Vice-Chairman* EDGAR MACNAUGHTON
R. A. SPENCE, *Secretary-Treasurer* G. K. SAURWEIN
Junior Group Chairman: F. ROBERT HARTIN
Junior Group Secretary: R. A. SPENCE

BRIDGEPORT

Organized: 1917, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: Fairfield County, Conn.
Place of Meeting: Stratfield Hotel
Local Organization: Engineers' Club of Bridgeport
Number of Members: 118

BRIDGEPORT (*continued*)

EXECUTIVE COMMITTEE

A. H. BEEDE, *Chairman*
C. N. HOAGLAND, *Vice-Chairman*
W. H. SNIFFEN, *Secretary*
A. W. HAGAN, *Treasurer*
T. H. BEARD
H. PATTERSON HARRIS
A. H. MOGENSEN
R. O. MOODY
O. J. RICHMOND
D. E. STEER
J. H. VAN YORX, JR.
H. E. WELLS
Junior Group Chairman: A. H. BEEDE
Junior Group Secretary: D. E. STEER

BUFFALO

Organized: 1915
Territory: Radius of thirty miles from Buffalo, N.Y.
Place of Meeting: Hotel Statler
Local Organization: Engineering Society of Buffalo
Number of Members: 175

EXECUTIVE COMMITTEE

PAUL DUBOSCLARD, *Chairman*
E. K. NICHOLSON, *Vice-Chairman*
W. A. MILLER, *Secretary*
C. E. HARRINGTON, *Treasurer*
W. M. KAUFMAN
E. J. WEITZMAN
J. L. YATES

CENTRAL ILLINOIS

Organized: 1937
Territory: All the territory in Central Illinois between the following counties on the northern boundary: Bureau, LaSalle, Knox, Stark, Putnam, Marshall, Livingston, Peoria; counties on the southern boundary: Pike, Scott, Morgan, Sangamon, Macon, Piatt, Douglas, and Edgar
Place of Meeting: Place varies
Local Organization: Indiana Engineering Society

EXECUTIVE COMMITTEE

L. P. WEINER, *Chairman*
C. A. DAVIS, JR., *Vice-Chairman*
R. T. MEES, *Secretary-Treasurer*
Junior Group Chairman: W. L. ACKERMAN
F. L. DAVIS
O. A. LEUTWILER
R. E. LUNEY

CENTRAL INDIANA

Organized: 1916
Territory: Radius of eighty miles from Indianapolis, within Indiana
Place of Meeting: Place varies
Local Organization: Indiana Engineering Society
Number of Members: 127

EXECUTIVE COMMITTEE

C. M. GROSS, *Chairman*
H. H. SKABO, *Vice-Chairman*
R. W. UPDIKE, *Secretary-Treasurer*
J. A. DROGUE
H. L. SOLBERG
J. S. TATMAN

CENTRAL PENNSYLVANIA

Organized: 1921
Territory: Radius of approximately sixty miles from State College, Pa.
Place of Meeting: Pennsylvania State College, State College, Pa.
Number of Members: 72

EXECUTIVE COMMITTEE

F. C. STEWART, *Chairman*
J. O. P. HUMMEL, *Secretary-Treasurer*
A. H. ZERBAN
C. L. ALLEN
R. L. ANTHONY

CHARLOTTE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of seventy-five miles from Charlotte, N.C.
Luncheon Meeting every Monday at 1:00 p.m. at Efirds Department Store
Number of Members: 39

EXECUTIVE COMMITTEE

A. W. BOLLENBACK, *Chairman*
R. P. REECE, *Vice-Chairman*
W. W. LEROY, *Secretary-Treasurer*
M. D. THOMASON
ASA HOSMER
F. R. JACKSON
W. E. MCDOWELL

CHICAGO

Organized: 1913
Territory: Radius of fifty miles from Chicago, Ill.
Headquarters: Mid-West A.S.M.E. Office, Room 1617, 205 West Wacker Drive, Chicago, Ill.
Luncheon Meeting every Tuesday at 12:15 p.m. at Chicago Engineers' Club
Local Organization: Western Society of Engineers
Number of Members: 757

EXECUTIVE COMMITTEE

R. E. TURNER, *Chairman*
L. M. ELLISON, *Vice-Chairman*
F. C. EVERITT, *Vice-Chairman*
H. F. HEBLEY, *Vice-Chairman*
B. D. STEVENS, *Vice-Chairman*
F. B. ORR, *Secretary-Treasurer*
C. C. AUSTIN
A. D. BAILEY
H. M. BLACK
HUGO DIEMER
W. E. DUNHAM
ROBERT ERICKSON
J. A. FOLSE
CHARLES GOLLIN
A. H. JENS
J. S. KOZACKA
F. H. LANE
T. S. MCEWAN
C. W. PARSONS
H. S. PHILBRICK
DANIEL ROESCH
M. W. SHERWOOD
A. F. SPITZGLASS
W. H. WINTERROWD
Junior Group Chairman: CHARLES GOLLIN
Junior Group Secretary: W. R. STEUR

CINCINNATI

Organized: 1912
Territory: Radius of thirty miles from Cincinnati, Ohio
Place of Meeting: Engineers' Club Rooms, Ninth & Race Sts.
Local Organization: Engineers' Club of Cincinnati
Number of Members: 171

EXECUTIVE COMMITTEE

EDWARD MARTIN, *Chairman*
SOL EINSTEIN, *Vice-Chairman*
R. STARR PARKER, *Secretary-Treasurer*
D. S. BROWN
E. H. MITSCH
Junior Group Chairman: R. L. SMITH
T. B. MORRIS
E. H. SCHUBERT
R. L. SMITH
C. E. SOMOGYI
H. P. THOMPSON

CLEVELAND

Organized: 1918
Territory: Counties of Lorain, Cuyahoga Lake, Geauga, and Ashtabula in Ohio
Place of Meeting: Statler Hotel
Local Organization: Cleveland Engineering Society
Luncheon Meeting every Wednesday at 12:30 p.m. at Hotel Statler Cafeteria
Number of Members: 247

EXECUTIVE COMMITTEE

H. A. SCHWARTZ, *Chairman*
G. B. CARSON, *Vice-Chairman*
E. R. MCCARTHY, *Secretary*
F. A. BARNES, *Treasurer*
Junior Group Chairman: A. K. PHELPS
Junior Group Secretary: J. O. GEISSBUHLER
A. E. GIBSON
E. L. LINDSETH
J. M. MAIN
R. R. SLAYMAKER

COLORADO

Organized: 1919
Territory: Entire State of Colorado
Place of Meeting: Parisienne Rotisserie Inn, Denver, Colo.
Local Organization: Colorado Engineering Council (Colorado Society of Engineers)
Number of Members: 83

EXECUTIVE COMMITTEE

A. L. HILL, *Chairman*
R. F. THRONE, *Secretary-Treasurer*
G. E. BEATTY
L. D. CRAIN
J. T. STRATE
J. A. HUNTER
F. H. PROUTY
G. A. RICHTER
S. L. SIMMERING

COLUMBUS

Organized: 1920
Territory: Counties of Union, Delaware, Licking, Madison, Franklin, Fayette, Pickaway, and Ross in Ohio

COLUMBUS (*continued*)

Place of Meeting: Battelle Memorial Institute and The Ohio State University
Local Organization: Engineers' Club of Columbus
Luncheon Meeting third Friday of each month at 12:00 noon at Engineers' Club, Columbus
Number of Members: 75

Executive Committee

W. A. Welcker, Jr., *Chairman*
R. N. Tucker, *Vice-Chairman*
R. C. Cross, *Secretary-Treasurer*
S. R. Beitler
H. N. Booker
H. M. Faust
C. P. Roberts
E. M. Sampson

DAYTON

Organized: 1926
Territory: Counties of Drake, Miami, Champaign, Preble, Montgomery, Greene, and northern part of Butler and Warren in Ohio
Place of Meeting: Engineers' Club of Dayton
Local Organization: Engineers' Club of Dayton
Number of Members: 75

Executive Committee

C. L. Bauer, *Chairman*
B. F. Downey, *Vice-Chairman*
E. L. Hutsel, *Secretary*
B. E. Tate, Jr., *Treasurer*
F. W. Williams
H. M. Gano
P. H. Kemmer
R. W. Martin
A. L. Paschall

DETROIT

Organized: 1916
Territory: Radius of thirty miles from Detroit, Mich.
Place of Meeting: Place varies
Local Organization: Engineering Society of Detroit
Number of Members: 433

Executive Committee

M. W. Benjamin, *Chairman*
B. W. Beyer, Jr., *Secretary-Treasurer*
J. W. Armour
J. A. Carlin
G. C. Daniels
J. J. Grebe
J. F. Jarnagin
T. W. Jeffords
H. E. Keeler
D. E. McGuire
J. P. Schechter
C. J. Freund, *Ex-Officio*
Junior Group Chairman: R. K. Weldy
Junior Group Secretary: O. F. Zehn

EAST TENNESSEE

Organized: 1922
Territory: All counties in Tennessee east of the west boundary of Scott, Morgan, Cumberland, White, Warren, Coffee, Moore, Franklin; Belle County in Kentucky; and Rossville, Dade, Walker, Cattasa, Whitfield, Murray, Gordon, Chattooga in Georgia
Place of Meeting: Place varies
Local Organization: Chattanooga Engineers Club and Knoxville Technical Club
Luncheon Meeting every Monday noon at Chattanooga Engineers Club
Number of Members: 93

Chattanooga Executive Committee

Newell Sanders, *Honorary Chairman*
T. C. Ervin, *Chairman*
H. H. Bailey, *Vice-Chairman*
G. S. Myers, *Secretary-Treasurer*
M. P. Wall

Knoxville Executive Committee

James Ellis, *Chairman*
W. R. Chambers, *Vice-Chairman*
J. M. Kaderly, *Secretary*
D. B. Benscoter
John Callan
D. R. Shearer
J. A. Switzer
Elmer Torok

ERIE

Organized: 1917
Territory: Radius of thirty miles from Erie, Pa.
Place of Meeting: Auditorium of Pennsylvania Telephone Company
Number of Members: 69

ERIE (*continued*)

Executive Committee

C. T. Oergel, *Chairman*
W. L. Hunter, *Secretary*
E. C. Ims, *Treasurer*
G. W. Bach
B. S. Cain
H. E. Goetz
W. L. McClaren
H. G. Mueller
M. S. Reed
R. W. Rogers

FLORIDA

Organized: 1925
Territory: State of Florida
Place of Meeting: Place varies
Local Organization: Florida Engineering Society, Gainesville, Fla.
Number of Members: 68

Executive Committee

Robert Peyinghaus, *Chairman*
N. C. Ebaugh, *First Vice-Chairman*
J. H. Clouse, *Second Vice-Chairman*
P. O. Yeaton, *Secretary-Treasurer*
M. H. C. Brombacher
W. E. Drew
A. B. Hale
John Hunter
A. J. Strong
T. F. Koch, *Student Chairman*
Junior Group Chairman: Robert Peyinghaus

GREEN MOUNTAIN

Organized: 1923
Territory: Entire State of Vermont and neighboring and closely related communities of Claremont and Hanover, N.H.
Place of Meeting: Springfield, Windsor, Vt., and Claremont, N.H.
Local Organization: Vermont Engineering Society
Number of Members: 34

Executive Committee

C. J. Dewell, *Chairman*
Leif Fersing, *Secretary-Treasurer*
M. H. Arms
C. S. Beach
J. B. Johnson
P. M. Klein
H. J. Lockwood
E. L. Sussdorff

GREENVILLE

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Greenville, S.C.
Place of Meeting: Meetings held at Greenville, Clemson College, S.C., Canton, Asheville, and Enka, N.C.
Number of Members: 37

Executive Committee

H. H. Iler, *Chairman*
R. S. Pruitt, *Vice-Chairman*
J. H. Sams, *Secretary-Treasurer*
B. E. Fernow
J. R. Gill
C. E. Hoey
J. A. McPherson
J. E. Waldrep

HARTFORD

Organized: 1917, as Branch of Conn. Section; reorganized, 1923
Territory: Hartford County except that portion served by Meriden and New Britain Sections
Place of Meeting: Hartford Electric Light Company
Number of Members: 119

Executive Committee

G. R. Truedsson, *Chairman*
S. A. Brandenburg, *Vice-Chairman*
R. D. Keller, *Secretary-Treasurer*
P. J. Cubeta
R. F. Dow
William Ferguson
E. P. Herrick
F. O. Hoagland
D. K. Morgan
W. S. Paine
R. S. Shaw
S. Jay Teller
H. B. Van Zelm
J. C. Ward, Jr.
Junior Group Chairman: G. C. Leitch
Junior Group Secretary: J. S. Eyster

INLAND EMPIRE

Organized: 1921
Territory: East of Columbia River in State of Washington, and Counties of Okanogan and Benton, and part of Northern Idaho
Place of Meeting: Davenport Hotel, Spokane
Luncheons Wednesdays at 12:00 noon, Davenport Hotel, Spokane
Local Organization: Associated Engineers of Spokane
Number of Members: 32

INLAND EMPIRE (*continued*)

EXECUTIVE COMMITTEE

E. B. PARKER, *Chairman*
A. R. KARLSTON, *Secretary-Treasurer*
H. F. GAUSS
D. R. GRAY

ITHACA

Organized: 1936
Territory: Radius of thirty miles from Ithaca plus following cities: Binghamton, Corning, Endicott, Geneva, Painted Post
Place of Meeting: Willard Straight Hall, Cornell Campus, Ithaca, N.Y.
Number of Members: 91

EXECUTIVE COMMITTEE

W. M. SAWDON, *Chairman*
E. F. MURPHY, JR., *Vice-Chairman*
F. S. ERDMAN, *Secretary-Treasurer*
CHRISTIAN FYNBOE
L. W. MORROW
F. G. SWITZER
M. P. WHITNEY

KANSAS CITY

Organized: 1921
Territory: Radius of sixty miles from Kansas City, Mo.
Place of Meeting: University Club
Local Organization: Engineers' Club of Kansas City
Number of Members: 127

EXECUTIVE COMMITTEE

W. B. ROLLINS, *Chairman*
H. L. CRAIN, *Vice-Chairman*
R. V. SUTHERLAND, *Secretary*
J. R. STONE, *Treasurer*
H. A. ATWATER
C. E. BECK
C. E. BROWN
E. D. HAY
LINN HELANDER
H. A. SMITH
W. E. WIDAU

Junior Group Chairman: RAYMOND HAHN
Junior Group Secretary: R. F. GLORE

LOS ANGELES

Organized: 1915
Territory: South of southern boundaries of following counties: Monterey, Kings, Tulares, and Inyo, Calif.
Place of Meeting: Barker Bros. Store
Local Organization: Technical Societies of Los Angeles
Luncheon Meetings Thursdays at 12:00 noon at Engineers' Club
Number of Members: 416

EXECUTIVE COMMITTEE

S. F. DUNCAN, *Chairman*
EARL MENDENHALL, *Vice-Chairman*
H. S. HOUGHTON, *Secretary-Treasurer*
W. H. CLAPP
D. S. CLARK
ALADAR HOLLANDER
SCOTT JENSEN
H. M. PERRY
C. H. SMITH
E. M. WAGNER
A. W. WELLS

Junior Group Chairman: EDMOND WAGNER
Junior Group Secretary: A. S. GREEN

LOUISVILLE

Organized: 1922
Territory: Radius of thirty miles from Louisville, Ky.
Place of Meeting: Engineers and Architects Club of Louisville
Local Organization: Engineers and Architects Club
Number of Members: 45

EXECUTIVE COMMITTEE

H. H. FENWICK, *Chairman*
RAY HASSELBERGER, *Vice-Chairman*
L. L. AMIDON, *Secretary*
V. E. FURNAS, JR., *Treasurer*
L. R. JACKSON
M. R. RABUCK
J. H. ROMANN
MELVIN SACK

MEMPHIS

Organized: 1923
Territory: Radius of sixty miles from Memphis, Tenn., and eastern half of Arkansas including all the territory east of a line drawn north and south through the western boundary of the city of Little Rock
Number of Members: 26

MEMPHIS (*continued*)

EXECUTIVE COMMITTEE

M. D. RUST, *Chairman*
W. J. FRANSIOLI, JR., *Vice-Chairman*
R. B. H. SHEPHERD, *Secretary-Treasurer*
T. H. ALLEN
C. M. MCCORD
W. H. ROBERTS

METROPOLITAN

Organized: 1910
Territory: Metropolitan District, New York and New Jersey
Place of Meeting: Engineering Societies Building, New York, N.Y.
Number of Members: 3380

EXECUTIVE COMMITTEE

J. M. DRISCOLL, *Chairman*
O. B. SCHIER, II, *Secretary*
A. F. ERNST, *Treasurer*
T. B. ALLARDICE
E. J. BILLINGS
E. H. FEZANDIE
C. A. HESCHELES
R. T. LIVINGSTON
W. MCC. MCKEE
A. R. MUMFORD
THEODORE BAUMEISTER, JR., *Ex-Officio*

Junior Group Chairman: H. B. FERNALD
Junior Group Secretary: SIDNEY DAVIDSON

MID-CONTINENT

Organized: 1919
Territory: Entire state of Oklahoma; territory in Arkansas not included in Memphis Section; part of Louisiana; and territory in Texas north of the southern boundaries of the counties of Gaines, Dawson, Bordon, Scurry, Fisher, Jones, and Shackelford
Place of Meeting: Tulsa Club
Number of Members: 140

EXECUTIVE COMMITTEE

D. K. HUTCHCRAFT, *Chairman*
G. RAYMOND, *Vice-Chairman*
L. C. PRICE, *Vice-Chairman*
A. G. BLANCHARD, *Vice-Chairman*
HERMAN WIENECKE, *Secretary*
W. L. DUCKER, *Treasurer*
E. E. AMBROSIUS
R. G. AYERS
E. C. BAKER
H. B. BERNARD
W. G. HELTZEL
EMORY KEMLER
A. J. KERR
HENRY SCHAEFER
H. T. SEARS
W. F. STEWART
F. A. STIVERS

Junior Group Chairman: W. F. STEWART

MILWAUKEE

Organized: 1904
Territory: Radius of fifty miles from Milwaukee, Wis.
Place of Meeting: Milwaukee Athletic Club
Local Organization: Engineers' Society of Milwaukee
Number of Members: 204

EXECUTIVE COMMITTEE

R. C. NEWHOUSE, *Chairman*
P. P. FICNERSKI, *Secretary*
W. D. BLISS
HANS DAHLSTRAND
F. H. DORNER
T. F. ESSERKALN
A. H. LUDICKE
ARTHUR SIMON
L. H. STARK

Junior Group Chairman: RUSSELL HAHN
Junior Group Secretary: W. T. SAVELAND, JR.

MINNESOTA

Organized: Minneapolis, 1913; St. Paul, 1913; the two Sections merged, 1934
Territory: Entire State of Minnesota
Place of Meeting: Minnesota Union
Local Organization: Minneapolis Engineers' Club, Minnesota Federation of Architectural and Engineering Societies
Number of Members: 98

EXECUTIVE COMMITTEE

E. B. CURRY, *Chairman*
K. A. POWELL, *Vice-Chairman*
BERTRAM GETSUG, *Secretary-Treasurer*
L. A. BRENEMAN
A. R. FORD
P. S. VAN WYCK

NEBRASKA

Organized: 1922
Territory: State of Nebraska, and Council Bluffs, Iowa

NEBRASKA (*continued*)

Place of Meeting: Lincoln and Omaha
Local Organization: Engineers' Club of Lincoln and Omaha
Luncheon Meeting every Wednesday noon at the Omaha Engineers' Club
Number of Members: 33

EXECUTIVE COMMITTEE

C. F. MOULTON, *Chairman*
H. N. BARNARD, *Vice-Chairman*
G. A. ROGERS, *Secretary-Treasurer*
J. W. BURNETT
OTTO JABELMANN
J. W. WHITE

NEW BRITAIN

Organized: 1921, as a Branch of Connecticut Section; reorganized as a Section, 1923
Territory: New Britain, Plainville, Forestville, Bristol, Kensington, and Berlin, Conn.
Place of Meeting: Auditorium of the State Trade School
Number of Members: 40

EXECUTIVE COMMITTEE

C. C. STEVENS, *Chairman*
W. C. ZINCK, *Vice-Chairman*
H. D. MARTIN, *Secretary-Treasurer*
P. W. BAUER
N. F. HJERPE
J. A. HUTCHINSON
B. S. LEWIS
S. H. STONER

NEW HAVEN

Organized: 1912; reorganized, 1923
Territory: Portions of New Haven and Middlesex Counties, Conn.
Place of Meeting: Mason Laboratory, Yale University
Number of Members: 83

EXECUTIVE COMMITTEE

F. W. KEATOR, *Chairman*
L. H. VON OHLSEN
A. L. BRECKENRIDGE
I. T. HOOK
R. A. NORTH
W. L. TANN
W. F. THOMPSON

NEW ORLEANS

Organized: 1916
Territory: All of Louisiana except the northern part allotted to Mid-Continent Section
Place of Meeting: Room 422, St. Charles Hotel
Local Organization: Louisiana Engineering Society
Number of Members: 95

EXECUTIVE COMMITTEE

K. P. KAMMER, *Chairman*
L. J. LASSALLE, *Vice-Chairman*
G. R. HAMMETT, *Secretary-Treasurer*
L. J. CUCULLU
J. S. HUEY
J. K. MAYER
A. D. REMANJON

Junior Group Chairman: L. J. CUCULLU
Junior Group Secretary: W. S. NELSON

NORTH TEXAS

Organized: 1922
Territory: Radius of one hundred and twenty-five miles from Dallas, in Texas
Place of Meeting: Dallas Power & Light Co. Bldg.
Local Organization: Technical Club of Dallas
Number of Members: 87

EXECUTIVE COMMITTEE

W. B. GREGORY, *Chairman*
N. G. HARDY, *Vice-Chairman*
F. C. JUSTICE, *Secretary-Treasurer*
H. R. PEARSON
H. M. ROBINSON
R. W. SALISBURY
RICHARD WERNER

Junior Group Chairman: L. S. COLE

NORWICH

Organized: 1930
Territory: Counties of Tolland, Windham, and New London in Connecticut, and Westerly District in Rhode Island
Place of Meeting: Arcanum Club, 150 Main St., Norwich
Number of Members: 37

(NORWICH *continued*)

EXECUTIVE COMMITTEE

F. S. ENGLISH, *Chairman*
E. S. DENNISON, *Vice-Chairman*
A. D. ANDRIOLA, *Secretary*
LOVELOCK HOLM
HANS LUEHRS
ERNEST NIBBS
F. E. REED

Junior Group Chairman: F. E. REED

ONTARIO

Organized: 1917
Territory: Province of Ontario, Canada
Place of Meeting: Mining Building, University of Toronto
Number of Members: 160

EXECUTIVE COMMITTEE

W. G. MCINTOSH, *Chairman*
G. E. ELLSWORTH, *Secretary-Treasurer*
T. C. AGNEW
O. H. ANDERSON
W. S. BALL
J. R. BURGESS
S. G. CLARKE
D. F. CORNISH
F. G. EAST
R. B. ELLIOTT
O. W. ELLIS
R. L. RUDE
WILLIAM SANGSTER

OREGON

Organized: 1919
Territory: State of Oregon and that territory in Washington within a radius of thirty miles from Portland, Ore.
Place of Meeting: Portland Hotel, Portland, Ore.
Local Organization: Oregon Society of Engineers
Number of Members: 53

EXECUTIVE COMMITTEE

E. N. BATES, *Chairman*
R. B. ROWAN, *Secretary*
F. L. DAVIS
P. L. HESLOP
LAWRENCE SUPOVÉ

Junior Group Chairman: J. C. OTHUS

PENINSULA

Organized: 1923
Territory: West of the east boundaries of the following counties: Emmet, Charlevoix, Antrim, Kalkaska, Missaukee, Clare, Isabella, Gratiot, Clinton, Eaton, Calhoun, and Branch, Mich.
Place of Meeting: Grand Rapids, Mich.
Local Organization: Engineers' Club of Grand Rapids
Number of Members: 47

EXECUTIVE COMMITTEE

C. A. HAMILTON, *Chairman*
R. E. KLISE, *Secretary-Treasurer*
C. G. LOHMANN
E. E. NORMAN
B. E. PORTER

PHILADELPHIA

Organized: 1912
Territory: Counties of Bucks, Montgomery, Chester, Philadelphia, Delaware, Pa., and the State of Delaware
Place of Meeting: Philadelphia Engineers' Club, 1317 Spruce Street, Philadelphia, Pa.
Local Organization: Philadelphia Engineers' Club
Luncheon Meeting every Tuesday noon at Philadelphia Engineers' Club
Number of Members: 840

EXECUTIVE COMMITTEE

C. C. JONES, *Chairman*
E. L. HOPPING, *Vice-Chairman*
H. E. CORL, *Secretary-Treasurer*
L. P. HYNES
J. S. MOREHOUSE
COLEMAN SELLERS, 3D

Junior Group Chairman: J. H. PETERSON
Junior Group Secretary: J. P. CLARK

PITTSBURGH

Organized: 1920
Territory: Counties bounded by and including Beaver, Butler, Venango, Forest, Jefferson, Indiana, Somerset, Fayette, Greene, and Washington, Pa.
Place of Meeting: Engineers' Society of Western Pennsylvania, William Penn Hotel
Local Organization: Engineers' Society of Western Pennsylvania
Number of Members: 425

PITTSBURGH *(continued)*

EXECUTIVE COMMITTEE

B. M. HERR, *Chairman*
T. E. PURCELL, *Secretary*
K. F. TRESCHOW, *Treasurer*
W. D. CANON
W. M. FRAME
P. G. McVETTY

PLAINFIELD

Organized: 1921
Territory: Plainfield and territory included between Elizabeth, Bound Brook, Metuchen, and Watchung, N.J.
Place of Meeting: Elizabeth Carteret Hotel, Elizabeth, and Plainfield Masonic Temple, Plainfield
Local Organization: Plainfield Engineers Club, Singer Engineering Society
Number of Members: 181

EXECUTIVE COMMITTEE

R. S. BRESCKA, *Chairman*
D. V. WATERS, *Vice-Chairman*
JOSEPH KERR, *Secretary*
C. G. HOLMBERG, JR., *Treasurer*
W. A. APPLEGATE
JOHN HAYDOCK

PROVIDENCE

Organized: 1920
Territory: Radius of thirty miles from Providence, R.I.
Place of Meeting: Providence Engineering Society Building, 195 Angell St., Providence, R.I.
Local Organization: Providence Engineering Society
Number of Members: 157

EXECUTIVE COMMITTEE

F. S. BLACKALL, JR., *Chairman*
H. S. SIZER, *Vice-Chairman*
A. W. CALDER, *Secretary-Treasurer*
Z. R. BLISS
F. A. CHIFFELLE
J. D. ELDERT
E. W. FREEMAN
N. D. MACLEOD
A. W. MOULDER
S. A. VAULE

RALEIGH

Organized: As a Branch, 1923; as a Section, 1927
Territory: Radius of sixty miles from Raleigh, N.C.
Place of Meeting: N. C. State College, Raleigh, N.C.
Local Organization: N.C. Engineering Council, Raleigh Engineers Club
Number of Members: 33

EXECUTIVE COMMITTEE

E. G. HOEFER, *Chairman*
C. E. KERCHNER, *Vice-Chairman*
F. B. TURNER, *Secretary-Treasurer*
R. M. ROTHGEB
H. E. SATTERFIELD
I. W. SUMMERLIN

ROCHESTER

Organized: 1919
Territory: Radius of thirty miles from Rochester, N.Y.
Place of Meeting: Rochester Engineering Society Rooms, Sagamore Hotel
Local Organization: Rochester Engineering Society, Sagamore Hotel
Luncheon Meeting every Tuesday at 12:15 p.m. at Sagamore Hotel
Number of Members: 100

EXECUTIVE COMMITTEE

T. F. HOOKER, *Chairman*
M. D. LEE, *Vice-Chairman*
I. G. McCHESNEY, *Secretary-Treasurer*
R. H. BUSHLEY
K. B. CASTLE
W. T. COWELL

ROCK RIVER VALLEY

Organized: 1926
Territory: Radius of thirty miles from Rockford, Ill., plus members in Madison, Wis.
Local Organization: Rockford Engineering Society
Number of Members: 61

EXECUTIVE COMMITTEE

R. C. GLAZEBROOK, *Chairman*
C. A. JACOBSON, *Vice-Chairman*
W. C. VON FISCHER, *Secretary-Treasurer*
J. H. MANSFIELD
L. H. GEDDES
F. P. GRUTZNER
A. M. JOHNSON

ST. JOSEPH VALLEY

Organized: 1929
Territory: Counties of La Porte, Starke, Pulaski, St. Joseph, Marshall, Fulton, Elkhart, and Kosciusko in Indiana, and Cass and Berrien Counties in Michigan
Place of Meeting: Morningside Hotel, South Bend, Ind.
Local Organization: St. Joseph Valley Engineers' Club
Number of Members: 28

EXECUTIVE COMMITTEE

C. R. ADAMS, *Chairman*
C. C. WILCOX, *Vice-Chairman*
K. W. KNORR, *Secretary-Treasurer*

ST. LOUIS

Organized: 1909
Territory: Radius of thirty miles from St. Louis, Mo.
Place of Meeting: Place varies
Local Organization: Engineers' Club of St. Louis
Number of Members: 203

EXECUTIVE COMMITTEE

A. L. HEINTZE, *Chairman*
D. E. DICKEY, *Vice-Chairman*
G. V. WILLIAMSON, *Secretary-Treasurer*
C. J. COLLEY
A. K. HOWELL
G. L. SHANKS

SAN FRANCISCO

Organized: 1910
Territory: All territory north of the northern boundaries of the counties of San Luis Obispo, Kern, and San Bernardino
Place of meeting: Engineers' Club, 206 Sansome St.
Luncheon Meetings every Thursday at 12:00 noon at the Engineers' Club
Local Organization: San Francisco Engineers' Club
Number of Members: 378

EXECUTIVE COMMITTEE

K. B. ANDERSON, *Chairman*
W. H. ARCHER, *Vice-Chairman*
H. B. LANGILLE, *Secretary-Treasurer*
G. L. SULLIVAN
Junior Group Chairman: EDWIN C. FLOYD
V. F. ESTCOURT
G. H. RAITT
H. J. SMITH

SAVANNAH

Organized: 1923
Territory: Radius of 125 miles from Savannah in Georgia
Place of Meeting: Savannah Hotel
Local Organization: Engineers' Council of Savannah Chamber of Commerce
Number of Members: 20

EXECUTIVE COMMITTEE

L. C. ROESEL, *Chairman*
A. P. KEISKER, *Vice-Chairman*
T. R. JONES, *Secretary-Treasurer*
G. A. MERCER, JR.
A. M. ORMOND
B. J. SAMS

SCHENECTADY

Organized: As a Branch, 1919; as a Section, 1927
Territory: Radius of thirty miles from Schenectady, N.Y.
Place of Meeting: Edison Club Hall
Number of Members: 162

EXECUTIVE COMMITTEE

J. K. SALISBURY, *Chairman*
H. M. OTTO, *Vice-Chairman*
A. L. RUIZ, *Vice-Chairman*
E. E. PARKER, *Secretary*
O. L. WOOD, JR.
R. H. NORRIS, *Treasurer*
J. E. ANDERSON
S. L. JAMESON
A. L. KIMBALL

SOUTH TEXAS

Organized: 1919
Territory: South Texas and the northern part of the State not included in the North Texas Section territory
Place of Meeting: Electric Bldg., Houston, Tex.
Number of Members: 160

SOUTH TEXAS (*continued*)

EXECUTIVE COMMITTEE

D. D. ALTON, *Chairman*
J. J. KING, *Vice-Chairman*
R. M. GARRISON, *Secretary-Treasurer*
J. W. BERETTA
C. W. CRAWFORD
H. E. DEGLER
JOHN DOGGETT, JR.
W. F. HERBERT
F. M. LEVERETT
G. W. LOWTHER
J. H. POUND

SUSQUEHANNA

Organized: 1927
Territory: Counties of Cumberland, Dauphine, Lebanon, Adams, York, and Lancaster
Place of Meeting: Engineering Society of York
Local Organization: Engineering Society of York and Engineers' Society of Pennsylvania, Harrisburg, Pa.
Number of Members: 79

EXECUTIVE COMMITTEE

H. B. MARTIN, *Chairman*
E. D. CLARK
A. B. SNAVELY
O. G. WHEAT

SYRACUSE

Organized: 1920
Territory: Radius of thirty miles from Syracuse, N.Y.
Place of meeting: Ball Room of the Onondaga Hotel
Local Organization: The Technology Club of Syracuse
Number of Members: 93

EXECUTIVE COMMITTEE

M. B. MOYER, *Chairman*
D. V. SHETLAND, *Vice-Chairman*
H. T. AVERY
C. F. DIETZ
F. A. FAILMEZGER
R. C. PAUL

TOLEDO

Organized: 1920
Territory: Radius of thirty miles from Toledo, Ohio
Place of Meeting: University Club, Toledo, Ohio
Local Organization: Affiliated Technical Societies of Toledo
Number of Members: 56

EXECUTIVE COMMITTEE

H. O. KRANICH, *Chairman*
N. R. OHLER, *Secretary-Treasurer*
C. A. ALEXANDER
H. A. BENNETT
S. B. BROOTZKOOS
R. G. N. EVANS
CARL FRAUTSCHI
JOHN GILLETT
L. H. MIDDLETON
D. A. OBERST
WILBUR SCHROEDER
V. E. WALTERS
E. W. WEAVER

TRI-CITIES

Organized: 1920
Territory: Radius of thirty miles from Moline, Ill.
Place of Meeting: Rock Island, Ill., Moline, Ill., and Davenport, Iowa
Luncheon Meeting every Wednesday, Davenport Hotel, 12:00 noon
Number of Members: 65

EXECUTIVE COMMITTEE

R. M. BARNES, *Chairman*
R. A. CROSS, *Vice-Chairman*
C. A. CARLSON, *Secretary-Treasurer*
P. E. ANDERSON
E. G. ERICKSON
J. M. HARTMAN
Junior Group Chairman: C. A. HAND
Junior Group Secretary: W. A. RUMMERY

UTAH

Organized: 1923
Territory: State of Utah
Place of Meeting: University Club, Salt Lake City
Local Organization: Utah Society of Engineers
Number of Members: 35

EXECUTIVE COMMITTEE

W. H. TRASK, JR., *Chairman*
H. D. LANDES, *Vice-Chairman*
W. D. TURPIN, *Secretary-Treasurer*
JULIUS BILLETER
J. D. ROBERTS

VIRGINIA

Organized: 1919
Territory: State of Virginia
Place of Meeting: Richmond, Norfolk, Charlottesville, Roanoke, University, Petersburg
Local Organization: Central Virginia Engineers Club
Number of Members: 129

EXECUTIVE COMMITTEE

G. L. BASCOME, *Chairman*
R. V. TERRY, *Vice-Chairman*
J. B. JONES, *Secretary*
F. S. ROOP, JR., *Treasurer*
E. W. FARLEY
W. H. KNISKERN
C. H. MANNING
G. C. MOLLESON
ARTHUR ROBERTS, JR.

WASHINGTON, D.C.

Organized: 1919
Territory: District of Columbia
Place of Meeting: Auditorium, Potomac Electric Power Co., 10th & E Sts., Washington, D.C.
Number of Members: 207

EXECUTIVE COMMITTEE

A. T. DUPONT, *Chairman*
H. G. THIELSCHER, *Vice-Chairman*
C. E. MILLER, *Secretary-Treasurer*
W. B. ENSINGER
J. FULTON FOX
H. K. KUGEL
P. A. WILLIS

WATERBURY

Organized: 1917, as a Branch; reorganized as a Section, 1923
Territory: Litchfield County and a portion of New Haven County
Place of Meeting: Elton Hotel
Number of Members: 83

EXECUTIVE COMMITTEE

A. J. GERMAN, *Chairman*
H. P. HART, *Vice-Chairman*
W. C. SCHNEIDER, *Secretary-Treasurer*
W. P. DOOLITTLE
L. J. NIEKIRK
R. C. PERRY
Junior Group Chairman: G. N. TYACK
Junior Group Secretary: H. C. ASHLEY

WESTERN MASSACHUSETTS

Organized: 1922
Territory: Includes counties of Berkshire, Franklin, Hampden, and Hampshire
Place of Meeting: Highland Hotel, Springfield, Mass.
Local Organization: Engineering Society of Western Massachusetts
Number of Members: 87

EXECUTIVE COMMITTEE

LESTER CAMPBELL, *Chairman*
J. L. SCHERNER, *Vice-Chairman*
L. G. CARLTON, *Secretary-Treasurer*
A. E. BENSON
A. H. LEWIS
C. E. MAYNARD

WESTERN WASHINGTON

Organized: 1919
Territory: State of Washington west of Columbia River with exception of territory included in 30-mile radius of Portland, Ore.
Place of Meeting: Engineers' Club, Arctic Bldg., Seattle, Wash.
Local Organization: Seattle Engineers' Club
Luncheon Meetings daily at noon at Engineers' Club, Seattle
Number of Members: 84

EXECUTIVE COMMITTEE

B. T. MCMINN, *Chairman*
EDDY FLOODEEN, *Vice-Chairman*
R. E. WALTER, *Secretary-Treasurer*
H. L. ADAMS
L. G. HARTMAN
C. J. YOST, JR.

WEST VIRGINIA

Organized: 1925
Territory: State of West Virginia, South of Parallel 39
Place of Meeting: Charleston, W. Va.
Number of Members: 53

EXECUTIVE COMMITTEE

F. LEROY SCHAEFER, *Chairman*
C. L. JOHNSON, *Vice-Chairman*
H. B. HICKMAN, *Secretary-Treasurer*
B. B. BETTY, JR.
H. L. CARSPECKEN
E. R. HABICHT
F. D. RIPLEY
Junior Group Chairman: H. L. CARSPECKEN
Junior Group Secretary: J. WILLIAMS

WORCESTER

Organized: 1915
Territory: Radius of thirty miles from Worcester, Mass.
Place of Meeting: Sanford Riley Hall, Worcester Poly. Inst.
Local Organization: Worcester Engineering Society
Number of Members: 134

Executive Committee

R. F. Gow, *Chairman*
F. R. Jones, *Vice-Chairman*
R. H. Wood, *Secretary-Treasurer*
E. W. Armstrong
H. P. Crane
R. P. Kolb
Otto Muller
E. H. Smith
W. S. Snow

YOUNGSTOWN

Organized: 1928
Territory: Counties of Trumbull, Mahoning, and Columbiana in Ohio, and Mercer and Lawrence in Pennsylvania
Place of Meeting: Central Y.M.C.A., Youngstown, Ohio
Number of Members: 58

Executive Committee

J. D. Jones, *Chairman*
H. W. Smith, *Vice-Chairman*
C. W. Foard, *Secretary-Treasurer*
F. J. Bowers
C. J. Duby
E. O. Oyen
F. R. Schaeffer
R. J. Wean
J. L. Wick, Jr.

Student Branches

ARTICLE B6A, PAR. 20: The Standing Committee on Relations With Colleges shall, under the direction of the Council, have supervision of the Student Branches of the Society and of such work of the Society as aims to further the education of engineers through the colleges and schools of accepted standing.

STANDING COMMITTEE, RELATIONS WITH COLLEGES

F. V. LARKIN, *Chairman and Representative on the Council* (1939)

H. O. CROFT (1940)
E. W. O'BRIEN (1941)
A. C. CHICK (1942)
J. D. CUNNINGHAM (1943)

Advisory Members (1939)

H. E. DEGLER
S. F. DUNCAN
E. O. EASTWOOD
F. H. PROUTY
G. L. SULLIVAN

Junior Adviser: J. I. YELLOTT (1939)

* Faculty Adviser.

Special Research Committees

ARTICLE B6A, PAR. 24: The Standing Committee on Research shall advise the Council on the research work of the Society.

The first Standing Committee on Research was organized in 1909.

STANDING COMMITTEE

N. E. FUNK, *Chairman and Representative on the Council* (1939)
L. W. WALLACE (1940)
E. G. BAILEY (1941)
W. TRINKS (1942)
M. D. HERSEY (1943)

LUBRICATION

Appointed October, 1915, to investigate the fundamental problems of lubrication, to formulate results of investigations previously made, and to keep in touch with contemporary research in this field

(Reorganized May, 1936)

G. B. KARELITZ, *Chairman*
S. J. NEEDS, *Secretary*
A. L. BEALL
OSCAR BRIDGEMAN
W. E. CAMPBELL
HANS DAHLSTRAND
H. A. EVERETT
A. E. FLOWERS
J. C. GENIESSE
RAYMOND HASKELL
M. D. HERSEY
B. F. HUNTER
G. L. NEELY
B. L. NEWKIRK
A. E. NORTON
E. S. PEARCE
J. F. PELLY
ERNEST WOOLER

FLUID METERS

Appointed 1916 to develop the theory of fluid meters of all kinds and to report on the best methods for their installation and use

(Reorganized July, 1926)

R. J. S. PIGOTT, *Chairman*
J. R. CARLTON, *Secretary*
H. S. BEAN
S. R. BEITLER
R. K. BLANCHARD
B. O. BUCKLAND
LOUIS GESS
A. J. KERR
T. H. KERR
M. P. O'BRIEN
W. S. PARDOE
E. S. SMITH
L. K. SPINK
R. E. SPRENKLE
E. C. M. STAHL
T. R. WEYMOUTH
M. J. ZUCROW

THERMAL PROPERTIES OF STEAM

Appointed in December, 1921, to direct research on the thermal properties of water-vapor and steam from 0 C to the upper limits of temperature and pressure

(Reorganized April, 1929)

G. L. BOURNE, *Chairman*
W. L. ABBOTT, *Vice-Chairman*
H. N. DAVIS
H. C. DICKINSON
ALEX DOW
A. M. GREENE, JR.
R. C. H. HECK
D. S. JACOBUS
MAX JAKOB
J. H. KEENAN
F. G. KEYES
L. S. MARKS
G. A. ORROK
R. J. S. PIGOTT
H. V. RASMUSSEN
E. L. ROBINSON

STRENGTH OF GEAR TEETH

Appointed in December, 1921. Is investigating factors affecting the strength and life of gear teeth

R. E. FLANDERS, *Chairman*
C. H. LOGUE, *Secretary*
C. G. BARTH
EARLE BUCKINGHAM
A. M. GREENE, JR.
C. W. HAM
F. E. MCMULLEN
E. W. MILLER
ERNEST WILDHABER

CUTTING OF METALS

Appointed in September, 1923. Is studying the problems of metal cutting, including tool materials, tool design, lubrication, cooling, and speeds and fuels

M. F. JUDKINS, *Chairman*
L. N. GULICK, *Secretary*
L. P. ALFORD
O. W. BOSTON
R. C. DEALE
A. L. DELEEUW
C. M. THOMPSON, JR.

MECHANICAL SPRINGS

Appointed May, 1924, to determine the status of the mechanical-spring art, to promote and conduct necessary and adequate research, and to develop the art to the point of standardization

J. R. TOWNSEND, *Chairman*
C. T. EDGERTON, *Secretary*
C. E. BARBA
W. G. BROMBACHER
R. W. COOK
W. T. DONKIN
RUPEN EKSERGIAN
G. E. HANSEN
BENJAMIN LIEBOWITZ
DAVID LOFTS
(R. D. BRIZZOLARA, *Alternate*)
D. J. MCADAM, JR.
R. E. PETERSON
J. B. REYNOLDS
J. W. ROCKEFELLER, JR.
B. W. ST. CLAIR
M. F. SAYRE
T. R. WEBER
KEITH WILLIAMS
J. K. WOOD
F. P. ZIMMERLI
O. B. ZIMMERMAN

ELEVATORS

Appointed June, 1924, as a subcommittee of the Sectional Committee on Safety Code for Elevators, to study the function and operation of elevator safeties and buffers and their associated mechanisms and to develop methods of test for the approval of elevator safety devices

D. J. PURINTON, *Chairman*
O. P. CUMMINGS, *Vice-Chairman*
J. A. DICKINSON, *Secretary*
BASSETT JONES
D. L. LINDQUIST
M. G. LLOYD
J. J. MATSON
M. B. MCLAUTHLIN
W. S. PAINE

EFFECT OF TEMPERATURE ON THE PROPERTIES OF METALS

Appointed December, 1924, as a joint research committee of the A.S.T.M. and the A.S.M.E. to encourage the investigation and accumulation of data on the properties of metals used in the mechanic arts at extremely high and low temperatures

N. L. MOCHEL, *Chairman*
H. J. KERR, *Vice-Chairman*
J. W. BOLTON, *Secretary*
R. H. ABORN
W. H. ARMACOST
A. B. BAGSAR
A. D. BAILEY
F. E. BASH
E. S. DIXON
F. B. FOLEY
J. R. FREEMAN, JR.
H. J. FRENCH
H. W. GILLETT
A. J. HERZIG
G. F. JENKS
J. J. KANTER
C. E. MACQUIGG
P. E. MCKINNEY
E. L. ROBINSON
A. E. WHITE

Director, National Bureau of Standards, U.S. Department of Commerce
Representative of Bureau of Engineering, U.S. Navy Department

BOILER FEEDWATER STUDIES

Appointed March, 1925, as a Joint Research Committee of the American Boiler Manufacturers Association, American Railway Engineering Association, American Water Works Association, Edison Electric Institute, the American Society for Testing Materials, and the A.S.M.E. to study methods of analysis and treatment of boiler feedwater for stationary and railroad practice

EXECUTIVE COMMITTEE (Total personnel 41)

C. H. FELLOWS, *Chairman*
R. C. BARDWELL, *Vice-Chairman*
J. B. ROMER, *Secretary*
†A. G. CHRISTIE
R. E. COUGHLIN
B. W. DE GEER
MAX HECHT
†C. F. HIRSHFELD
H. E. JORDAN
W. F. KEENAN, JR.
P. B. PLACE
S. T. POWELL
F. N. SPELLER
M. F. STACK
E. H. TENNEY
†A. E. WHITE

CONDENSER TUBES

Appointed May, 1925, to investigate and report on the causes of failure of tubes used in steam condensers and similar heat interchange apparatus

A. E. WHITE, *Chairman*
BERT HOUGHTON, *Vice-Chairman*
P. A. BANCEL
D. K. CRAMPTON
H. M. CUSHING
R. E. DILLON
O. B. J. FRASER
J. R. FREEMAN, JR.
V. M. FROST
C. F. HARWOOD
C. F. HIRSHFELD
G. C. HOLDER
O. Z. KLOPSCH
H. W. LEITCH
E. F. MILLER
W. B. PRICE
M. F. STACK
H. A. STAPLES
W. R. WEBSTER
D. C. WEEKS

Director, Bureau of Engineering, U.S. Navy Department

BOILER FURNACE REFRACTORIES

Appointed June, 1925, to determine the principal factors governing the failure of refractories in various types of installations, to subject these factors to detailed experimental analysis, to undertake the formulation of suitability tests and, if necessary, to attempt to develop a suitable refractory to meet the needs of severe service

W. A. CARTER, *Chairman*
S. H. BARNUM
G. A. BOLE
M. C. BOOZE
W. H. FULWEILER
C. B. GRADY
R. A. HEINDL
C. F. HIRSHFELD
R. K. HURSH
N. E. LEWIS
J. S. MCDOWELL
(F. A. HARVEY, *Alternate*)
S. J. MCDOWELL
PERCY NICHOLLS
S. M. PHELPS
E. B. POWELL
R. A. SHERMAN
R. B. SOSMAN
L. J. TROSTEL
G. B. WILKES

WORM GEARS

Appointed May, 1927, to investigate certain problems in connection with the action of worm gear drives and to recommend improvements in their design, manufacture, and use

EARLE BUCKINGHAM, *Chairman*
G. H. ACKER
L. R. BUCKENDALE
W. H. HIMES
D. L. LINDQUIST
A. A. ROSS
B. F. WATERMAN

Representative of Bureau of Engineering, U.S. Navy Department

VELOCITY MEASUREMENT OF FLUID FLOW

Appointed October, 1927, to sponsor the development of an absolute method for determining the velocity of the flow of fluids by means of the location of nodal points in wave systems

W. F. DURAND, *Chairman*
T. R. WEYMOUTH

† Official A.S.M.E. representatives serving on this committee.

MEASURES OF MANAGEMENT

Appointed March, 1928, to attempt the reconciliation of certain economic laws affecting production, to develop formulas for management, and to collect and report information on management research

W. E. FREELAND, *Chairman*
F. E. RAYMOND, *Secretary*
J. H. BARBER
T. H. BROWN
R. C. DAVIS
G. E. HAGEMANN

ABSORPTION OF RADIANT HEAT IN BOILER FURNACES

Appointed April, 1928, to make a study of the absorption of radiant heat in boiler furnaces with the purpose of developing recommendations on improved furnace design

W. J. WOHLENBERG, *Chairman*
E. G. BAILEY
R. M. GATES
C. W. GORDON
E. L. LINDSETH
G. A. ORROK
R. J. S. PIGOTT
JOHN VAN BRUNT

STRENGTH OF VESSELS UNDER EXTERNAL PRESSURE

Appointed June, 1929, to develop reliable design data on the strength of cylindrical and spherical surfaces under external pressure, particularly with reference to jacketed vessels

W. D. HALSEY, *Chairman*
F. V. HARTMAN
M. B. HIGGINS
A. W. LIMONT, JR.
H. E. SAUNDERS
E. E. SHANOR
D. B. WESSTROM
F. S. G. WILLIAMS
D. F. WINDENBURG

WIRE ROPE

Appointed April, 1930, to investigate existing rope so that it may be better understood and more effectively used

W. H. FULWEILER, *Chairman*
H. LER. BRINK
D. L. LINDQUIST
G. W. MARTIN
C. A. MCCUNE
A. H. MCDOUGALL
B. V. E. NORDBERG, JR.
W. S. PAINE
W. J. RYAN
GEORGE SIMPSON
L. E. YOUNG

CRITICAL PRESSURE STEAM BOILERS

Appointed June, 1931, to study the characteristics of high-pressure forced-circulation steam-generating units

A. A. POTTER, *Chairman*
W. H. ARMACOST
A. D. BAILEY
E. G. BAILEY
A. G. CHRISTIE
F. S. CLARK
C. H. FELLOWS
H. J. KERR
M. W. LINK
G. A. ORROK
H. L. SOLBERG
P. W. THOMPSON

COTTONSEED PROCESSING

Appointed December, 1932, to study the mechanical problems involved in storing, conditioning, and cooking cottonseed meats

W. R. WOOLRICH, *Chairman*
HOMER BARNES
E. L. CARPENTER
C. E. GARNER
B. J. SAMS
R. B. TAYLOR

ROLLING OF STEEL (PLASTICITY)

Appointed October, 1938, to study plasticity in the particular field of rolling of steel

E. C. BAIN
C. L. EKSERGIAN
C. W. MACGREGOR
A. NÁDAI
MORRIS STONE

A.S.M.E. Representatives on Other Research Committees

See also A.S.M.E. Representatives on Other Activities, page RI-8

AMERICAN COORDINATING COMMITTEE ON CORROSION

American Society for Testing Materials

S. L. KERR
C. H. FELLOWS (*Alternate*)

CORROSION COMMITTEE

American Society of Refrigerating Engineers

(To be appointed)

FATIGUE PHENOMENA OF METALS

American Society for Testing Materials

C. T. EDGERTON

HEAT-TREATMENT OF ROCK DRILL STEELS

Advisory Board of the Bureau of Standards and Bureau of Mines

(To be appointed)

METALLURGICAL RESEARCH

Advisory Committee to the National Bureau of Standards

C. H. BIERBAUM

PROPERTIES OF REFRACTORY MATERIALS

Advisory Committee to the National Bureau of Standards

E. B. POWELL

WATER FOR INDUSTRIAL USES

American Society for Testing Materials

J. H. WALKER

Standardization Technical Committees

ARTICLE B6A, PAR. 23: The Standing Committee on Standardization shall advise the Council on the dimensional standardization work of the Society, including relations with the American Standards Association.

The first Standing Committee on Standardization was organized in April, 1911.

STANDING COMMITTEE

O. A. LEUTWILER, *Chairman and Representative on the Council* (1939)
W. C. MUELLER (1940)
A. L. BAKER (1941)
J. E. LOVELY (1942)
J. R. WEAVER (1943)

STANDARDIZATION AND UNIFICATION OF SCREW THREADS (B-1)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee originally organized in June, 1921. Reorganized in February, 1929*

A.S.M.E. Members (Total personnel, 36)

†R. E. FLANDERS, *Chairman*
EARLE BUCKINGHAM, *Secretary*
E. J. BRYANT
G. S. CASE
T. G. CRAWFORD
†A. M. HOUSER
H. C. E. MEYER
†P. V. MILLER
W. C. MUELLER
R. H. PERRY
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Scope, Arrangement, and Editing of American National Standard, R. E. FLANDERS
No. 2 on Terminology and Thread Specifications, Except Gages, C. W. BETTCHER
No. 3 on Special Threads and Twelve Pitch Series, Except Gages
No. 4 on Acme and Other Similar Threads, Except Gages, EARLE BUCKINGHAM
No. 5 on Screw Thread Gages and Inspection, G. S. CASE
No. 7 on Wood Screws, ARTHUR BOOR

BALL AND ROLLER BEARINGS (B-3)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized December, 1920*

A.S.M.E. Members (Total personnel, 14)

†W. P. KENNEDY, *Vice-Chairman*
†D. E. BATESOLE
L. A. CUMMINGS
F. G. HUGHES
†G. E. HULSE
L. F. NENNINGER
ERNEST WOOLER

* *Note:* All of the standards committees for which the Society is sponsor or joint sponsor, or on which it has representation, are organized under the procedure of the American Standards Association.

† Official A.S.M.E. representatives serving on this committee.

PIPE THREADS (B-2)

* *Joint sponsorship with the American Gas Association. Sectional Committee originally organized in 1913. Reorganized May, 1927*

A.S.M.E. Members (Total personnel, 49)

A. S. MILLER, *Chairman*
A. F. BREITENSTEIN
E. J. BRYANT
E. S. CORNELL, JR.
J. J. CROTTY
A. P. DENTON
J. J. HARMAN
†A. M. HOUSER
A. H. JARECKI
P. V. MILLER
F. H. MOREHEAD
W. C. MORRIS
S. F. NEWMAN
E. S. SANDERSON
L. N. SHANNON
W. D. SIZER
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 on Editing and Gaging, A. M. HOUSER
No. 2 on Taper Pipe Threads, S. B. TERRY
No. 3 on Straight Pipe Threads, A. S. MILLER
No. 4 on Plumbers' Threads, A. F. BREITENSTEIN
No. 5 on Screw Threads for Rigid Steel Conduit, JAMES BARTON
No. 6 on Special Threads for Thin Tubes, C. C. WINTER

ALLOWANCES AND TOLERANCES FOR CYLINDRICAL PARTS AND LIMIT GAGES (B-4)

**Sole sponsorship. Sectional Committee originally organized in June, 1920. Reorganized in September, 1930*

A.S.M.E. Members (Total personnel, 44)

†J. E. LOVELY, *Chairman*
F. E. BANFIELD, JR.
F. S. BLACKALL, JR.
E. J. BRYANT
†EARLE BUCKINGHAM
†F. H. COLVIN
T. G. CRAWFORD
R. E. W. HARRISON
F. O. HOAGLAND
N. E. JACOBI
H. C. E. MEYER
P. V. MILLER
W. C. MUELLER
†E. C. PECK
R. H. PERRY
W. C. SCHOENFELDT
C. C. STEVENS
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMAN

No. 1 on Tolerance Systems, R. E. W. HARRISON

SMALL TOOLS AND MACHINE TOOL ELEMENTS (B-5)

** Joint sponsorship with the National Machine Tool Builders Association and the Society of Automotive Engineers.*
Sectional Committee organized September, 1922

A.S.M.E. Members (Total personnel, 25)

†W. C. Mueller, *Chairman*
F. O. Hoagland, *Vice-Chairman*
J. B. Armitage
F. S. Blackall, Jr.
O. W. Boston
E. J. Bryant
Earle Buckingham
†F. H. Colvin
S. A. Einstein
†H. E. Harris
John Haydock
J. E. Lovely
†E. R. Norris
Erik Oberg

C. W. Spicer

Technical Committee No. 1 on T-slots

A.S.M.E. Members (Total personnel, 9)

†Erik Oberg, *Chairman*
J. B. Armitage
†Harry Cadwallader, Jr.
Herman Casler
S. A. Einstein
†F. O. Hoagland

†E. R. Norris

Technical Committee No. 2 on Tool Posts and Tool Shanks

A.S.M.E. Members (Total personnel, 8)

O. W. Boston, *Chairman*
F. S. Blackall, Jr.
†Granger Davenport
M. E. Lange

Technical Committee No. 3 on Machine Tapers

A.S.M.E. Members (Total personnel, 20)

F. S. Blackall, Jr., *Chairman*
J. B. Armitage
†E. J. Bryant
†Earle Buckingham
F. H. Colvin
J. B. Dillard
(T. F. Githens, *Alternate*)
B. P. Graves
H. E. Harris
†F. O. Hoagland
J. H. Horigan
A. H. Lyon
L. F. Nenninger
C. W. Spicer

SUBGROUP CHAIRMEN

Steep Tapers Series, S. McMullan
Revision of Slow Taper Standard, E. J. Bryant

Technical Committee No. 4 on Spindle Noses and Collets for Machine Tools

A.S.M.E. Members (Total personnel, 26)

J. E. Lovely, *Chairman*
L. F. Nenninger, *Secretary*
J. B. Armitage
B. P. Graves
F. O. Hoagland
A. M. Johnson
M. E. Lange
J. H. Mansfield
H. W. Ruppel
L. D. Spence

SUBGROUP CHAIRMEN

No. 1 on Milling Machines, Small and Medium, J. B. Armitage
No. 2 on Large Milling Machines, F. B. Kampmeier
No. 3 on Grinding Machine Spindles, H. J. Griffing
No. 5 on Drilling Machines and Horizontal Boring Machines, S. McMullan
No. 6 on Turning Machines, Including Automatic Screw Machines, Lathes, Automatic Lathes, Turret Lathes, and Automatic Chucking Machines, J. E. Lovely
No. 7 on Cutting and Hobbing Machines, A. L. Stewart
No. 8 on Correlation of Counter Proposals for Spindle Noses, J. E. Lovely

Technical Committee No. 5 on Milling Cutters

A.S.M.E. Members (Total personnel, 20)

J. B. Armitage
†A. N. Goddard
J. H. Horigan
G. L. Markland, Jr.
E. K. Morgan
†Erik Oberg

E. D. Vancil

SUBGROUP CHAIRMEN

No. 1 on Profile Cutters, E. D. Vancil
No. 2 on Keyways, J. B. Armitage
No. 3 on Nomenclature, A. C. Danekind
No. 4 on Limits, J. H. Horigan
No. 5 on Formed Cutters, H. C. Hungerford
No. 6 on Hobs, G. L. Markland, Jr.
No. 7 on Inserted Tooth Cutters, J. B. Armitage

Technical Committee No. 6 on Designations and Working Ranges of Machine Tools

A.S.M.E. Members (Total personnel, 19)

John Haydock, *Chairman*
Earle Buckingham
T. H. Doan, Jr.
B. P. Graves
J. J. McBride
E. R. Smith

Technical Committee No. 7 on Twist Drill Sizes

A.S.M.E. Members (Total personnel, 7)

W. C. Mueller, *Chairman*
J. H. Horigan

C. W. Spicer

Technical Committee No. 8 on Jig Bushings

A.S.M.E. Members (Total personnel, 8)

J. H. Horigan
H. E. Wells

Technical Committee No. 9 on Punch Press Tools

A.S.M.E. Members (Total personnel, 16)

D. H. Chason
N. W. Dorman
H. E. Harris
D. M. Palmer

H. E. Wells

Technical Committee No. 10 on Forming Tools and Holders

A.S.M.E. Members (Total personnel, 9)

W. C. Mueller, *Chairman*
William Hartman
L. D. Spence
H. E. Wells

Technical Committee No. 11 on Chucks and Chuck Jaws

A.S.M.E. Member (Total personnel, 10)

J. E. Lovely, *Chairman*

SUBGROUP CHAIRMAN

No. 1 on Master Chuck Jaws, J. E. Lovely
No. 2 on Adapters for Air Cylinders, J. E. Lovely

Technical Committee No. 12 on Cut and Ground Thread Taps

(Total personnel, 7)

Technical Committee No. 13 on Splines and Splined Shafts

A.S.M.E. Members (Total personnel, 16)

C. W. Spicer, *Chairman*
J. B. Armitage
R. E. W. Harrison
F. O. Hoagland
J. E. Lovely
B. F. Waterman

SUBGROUP CHAIRMEN

Machine Tool Splines, R. E. W. Harrison
Automotive Splines, W. L. Barth
Involute Splines, C. K. Lenning

Technical Committee No. 17 on Nomenclature for Small Tools and Machine Tool Elements

A.S.M.E. Members (Total personnel, 15)

O. W. Boston, *Chairman*
F. S. Blackall, Jr.
F. H. Colvin
H. E. Harris

F. O. Hoagland

Ex-Officio Members

A. N. Goddard
B. P. Graves
W. C. Mueller
C. W. Spicer

H. E. Wells

Technical Committee No. 18 on Multiple Spindle Drilling Heads

A.S.M.E. Member (Total personnel, 9)

H. E. Wells

Technical Committee No. 19 on Single Point Cutting Tools

A.S.M.E. Members (Total personnel, 2)

F. H. Colvin, *Chairman*
O. W. Boston, *Secretary*

Technical Committee No. 20 on Reamers

A.S.M.E. Members (Total personnel, 16)

E. J. Bryant
F. H. Colvin
T. F. Githens
J. H. Horigan

H. E. Wells

GEARS (B-6)

* *Joint sponsorship with the American Gear Manufacturers Association. Sectional Committee organized June, 1921*

A.S.M.E. Members (Total personnel, 27)

B. F. Waterman, *Chairman*
†Earle Buckingham, *Vice-Chairman*
G. H. Acker
L. H. Fry
C. B. Hamilton, Jr.
D. T. Hamilton
M. R. Hanna
†O. A. Leutwiler
G. L. Markland, Jr.
H. E. Vehslage

Subcommittee Chairmen

No. 1 on Program, B. F. Waterman
No. 2 on Editing Reports, B. F. Waterman
No. 3 on Nomenclature, D. T. Hamilton
No. 4 on Tooth Form (Spur Gears), U. S. Eberhardt
No. 5 on Helical Gears, W. P. Schmitter
No. 6 on Worm Gears, T. R. Rideout
No. 7 on Bevel Gears, F. L. Knowles
No. 8 on Materials, C. B. Hamilton, Jr.
No. 9 on Inspection, J. P. Breuer
No. 10 on Horsepower Rating, Earle Buckingham

PIPE FLANGES AND FITTINGS (B-16)

* *Joint sponsorship with the Heating, Piping, and Air Conditioning Contractors National Association and the Manufacturers Standardization Society of the Valve and Fittings Industry. Sectional Committee organized October, 1921*

A.S.M.E. Members (Total personnel, 50)

†C. P. Bliss, *Chairman*
J. J. Harman, *Secretary*
†L. W. Benoit
A. L. Brown
W. R. Conard
Sabin Crocker
Ferdinand Fink
H. E. Haller
J. S. Hess
†H. A. Hoffer
E. L. Hopping
A. M. Houser
D. S. Jacobus
†C. A. Kelting
J. R. Kruse
(John Blizard, *Alternate*)
M. B. MacNeille
F. H. Morehead
†E. L. Moreland
L. S. Morse
Ludwig Skog
†J. R. Tanner
J. H. Taylor
H. L. Underhill
G. W. Watts
J. H. Williams

Subcommittee Chairmen

No. 1 on Cast Iron Flanges and Flanged Fittings, A. M. Houser
No. 2 on Screwed Fittings, F. H. Morehead
No. 3 on Steel Flanges and Flanged Fittings, C. P. Bliss
No. 4 on Materials and Stresses, A. M. Houser
No. 5 on Face to Face Dimensions of Ferrous Flanged Valves, J. R. Tanner
No. 6 on Malleable Iron or Steel Brass Seat Unions
No. 7 on Rating of Pipe Fittings
No. 8 on Marking of Pipe Fittings
No. 9 on Port Openings, W. W. Hubbard

BOLT, NUT, AND RIVET PROPORTIONS (B-18)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized March, 1922*

A.S.M.E. Members (Total personnel, 62)

†A. E. Norton, *Chairman*
H. E. Aldrich
F. C. Billings
B. G. Braine
(D. L. Braine, *Alternate*)
Ellwood Burdsall
G. S. Case
T. G. Crawford
H. P. Frear
Herman Koester
S. F. Newman
Martin Slifka
R. J. Whelan
E. M. Whiting
V. R. Willoughby
(J. J. McBride, *Alternate*)
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Large and Small Rivets, H. N. Wallin
No. 2 on Wrench Head Bolts and Nuts, H. B. Slocum
No. 3 on Slotted Head Proportions
No. 4 on Track Bolts and Nuts
No. 5 on Round Unslotted Head Bolts (Carriage Bolts), M. C. Horine
No. 6 on Plow Bolts, O. B. Zimmerman
No. 7 on Body Dimensions and Materials
No. 8 on Nomenclature, G. S. Case
No. 9 on Socket Head Cap and Set Screws, Herman Koester

SHAFTING (B-17)

* *Sole sponsorship. Organized October, 1918*

A.S.M.E. Members (Total personnel, 13)

†C. M. Chapman, *Chairman*
H. C. E. Meyer
L. C. Morrow
J. M. Shimer
C. W. Spicer
†G. N. Van Derhoef
†L. W. Williams

Subcommittee Chairmen

No. 1 on Shafting Dimensions, L. W. Williams
No. 2 on Stock Key Sizes
No. 3 on Code for Design of Transmission Shafting
No. 4 on Taper Keys, J. E. Bushnell
No. 5 on Woodruff Keys, L. C. Morrow

PLAIN AND LOCK WASHERS (B-27)

* *Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized August, 1925*

A.S.M.E. Members (Total personnel, 40)

Eugene Caldwell
T. G. Crawford
†B. S. Lewis
C. H. Loutrel
J. J. McBride
H. C. E. Meyer
E. M. Whiting
O. B. Zimmerman

Subcommittee Chairmen

No. 1 on Plain Washers
No. 2 on Lock Washers, C. H. Loutrel

TRANSMISSION CHAINS AND SPROCKETS (B-29)

**Joint sponsorship with the Society of Automotive Engineers and the American Gear Manufacturers Association. Sectional Committee organized September, 1917. Reorganized December, 1926*

A.S.M.E. Members (Total personnel, 15)

W. J. Belcher
†C. H. Jahnke
Joseph Joy
†L. V. Ludy
D. B. Perry
G. A. Young
O. B. Zimmerman

CODE FOR PRESSURE PIPING (B-31)

**Sole sponsorship. Sectional Committee organized March, 1926. Reorganized December, 1937*

A.S.M.E. Members (Total personnel, 101)

E. B. Ricketts, *Chairman*
R. E. Bryant
H. C. Cooper
D. H. Corey
Sabin Crocker
H. D. Edwards
Charles Fitzgerald
E. R. Fish
V. M. Frost
T. W. Greene
H. E. Haller
H. D. Halsey
J. S. Haug
(E. B. Severs, *Alternate*)
H. A. Hoffer
G. G. Hollins
E. L. Hopping
†A. M. Houser
†Alfred Iddles
D. S. Jacobus
T. M. Jasper
C. A. Kelting
G. S. Larsen
M. B. MacNeille
G. W. Martin
H. C. E. Meyer
J. W. Moore
(J. D. Capron, *Alternate*)
F. H. Morehead
(W. W. Crawford, *Alternate*)
(J. J. Harman, *Alternate*)
H. H. Morgan
L. S. Morse
A. W. Moulder
E. W. Norris
C. W. Obert
G. A. Orrok
A. L. Penniman, Jr.
†C. S. Robinson
J. H. Romann
G. W. Saathoff
G. K. Saurwein
Ludwig Skog
H. S. Smith
(H. H. Moss, *Alternate*)
F. N. Speller
J. R. Tanner
J. H. Taylor
J. H. Vance
H. LeR. Whitney
H. L. Whittemore
J. H. Williams
T. F. Wolfe

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan, Scope, and Editing, SABIN CROCKER
No. 2 on Power Piping, ALFRED IDDLES
No. 4 on Gas and Air Piping, J. S. HAUG
No. 5 on Refrigeration Piping, A. H. BAER
No. 6 on Oil Piping, A. D. SANDERSON
No. 7 on Piping Materials and Identification, F. H. MOREHEAD
No. 8 on Fabrication Details, LUDWIG SKOG
No. 9 on Code for District Heating Piping, G. K. SAURWEIN

WIRE AND SHEET METAL GAGING SYSTEMS (B-32)

**Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized November, 1927*

A.S.M.E. Members (Total personnel, 27)

J. F. HOWE — F. G. WILSON

SUBCOMMITTEE CHAIRMEN

No. 1 on Flat Stocks
No. 2 on Wires and Rods
No. 3 on Tubing, Piping, Conduit and Casing, F. H. NULLMEYER

SCREW THREADS FOR HOSE COUPLINGS (B-33)

**Sole sponsorship. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 28)

A. L. BROWN, *Secretary*
†A. F. BREITENSTEIN
J. J. CROTTY
W. L. CURTISS
†W. E. DUNHAM
J. J. HARMAN
(F. C. ERNST, *Alternate*)
A. M. HOUSER
H. C. E. MEYER
J. H. WILLIAMS

SUBCOMMITTEE CHAIRMEN

No. 1 to Draft Recommended Specifications, J. H. HOWLAND
No. 2 on Basic Thread Dimensions, D. R. MILLER

WROUGHT IRON AND WROUGHT STEEL PIPE AND TUBING (B-36)

**Joint sponsorship with the American Society for Testing Materials. Sectional Committee organized April, 1928*

A.S.M.E. Members (Total personnel, 44)

H. H. MORGAN, *Chairman*
SABIN CROCKER, *Secretary*
H. E. ALDRICH
E. L. HOPPING
(A. B. MORGAN, *Alternate*)
†A. M. HOUSER
†D. S. JACOBUS
†(F. S. CLARK, *Alternate*)
J. J. KANTER
H. C. E. MEYER
F. H. MOREHEAD
†H. B. OATLEY
†LUDWIG SKOG
F. N. SPELLER
J. R. TANNER
A. E. WHITE
H. LeR. WHITNEY

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan, Scope, and Editing, H. H. MORGAN
No. 2 on Pipe and Tubing for Low Temperature Service, J. J. SHUMAN
No. 3 on Pipe and Tubing for High Temperature Service, J. R. TANNER
No. 4 on Materials, F. H. MOREHEAD

PRESSURE AND VACUUM GAGES (B-40)

**Sole sponsorship. Sectional Committee organized July, 1930*

A.S.M.E. Members (Total personnel, 45)

M. D. ENGLE, *Chairman*
†A. W. LENDEROTH, *Secretary*
E. J. BRYANT
†J. P. CAVANAUGH
PAUL DISERENS
C. H. GRAESSER
W. F. JONES
R. J. KEHL
†J. C. McCUNE
A. H. MORGAN
H. B. REYNOLDS
W. C. SCHOENFELDT

SUBCOMMITTEE CHAIRMEN

No. 1 on Plan and Scope, M. D. ENGLE
No. 2 on Definitions, C. F. SCHWEP
No. 3 on Gage Sizes and Mounting Dimensions, H. B. REYNOLDS
No. 4 on Accuracy and Test Methods, O. J. HODGE

STOCK SIZES, SHAPES AND LENGTHS FOR HOT AND COLD FINISHED IRON AND STEEL BARS (B-41)

**Sole sponsorship. Sectional Committee organized April, 1929*

A.S.M.E. Members (Total personnel, 27)

F. H. DECHANT
†L. W. WILLIAMS
G. H. WOODROFFE
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Hot Rolled Steel, HENRY WYSOR
No. 2 on Cold Finished Steels, L. E. CREIGHTON
No. 3 on Hot Rolled Iron

SPECIFICATIONS FOR LEATHER BELTING (B-42)

**Sole sponsorship. Sectional Committee organized February, 1931*

A.S.M.E. Members (Total personnel, 27)

H. T. COATES
†R. W. DRAKE
KING HATHAWAY
J. E. RHOADS
G. A. SCHIEREN
†C. O. STREETER
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1 on Standard Specifications, R. C. BOWKER
No. 2 on Recommendations for Selection, Care, and Installation, G. A. SCHIEREN

MACHINE PINS (B-43)

**Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized, March, 1926*

A.S.M.E. Members (Total personnel, 16)

†E. J. BRYANT
J. J. McBRIDE
H. C. E. MEYER
O. B. ZIMMERMAN

SUBCOMMITTEES

No. 1 on Straight, Taper, and Dowel Pins
No. 2 on Split Pins

FOUNDRY EQUIPMENT AND SUPPLIES (B-45)

**Joint sponsorship with the American Foundrymen's Association. Sectional Committee organized February, 1931*

A.S.M.E. Members (Total personnel, 24)

E. S. CARMAN, *Chairman*
E. W. ELY
F. W. HERENDEEN
A. S. PHELPS
O. B. ZIMMERMAN

SUBCOMMITTEE CHAIRMEN

No. 1, L. M. SHERWIN
No. 2, E. S. CARMAN
No. 3, A. S. PHELPS

CLASSIFICATION AND DESIGNATION OF SURFACE QUALITIES (B-46)

**Joint sponsorship with the Society of Automotive Engineers. Sectional Committee organized May, 1932*

A.S.M.E. Members (Total personnel, 63)

J. R. WEAVER, *Chairman*
E. J. ABBOTT
E. J. BRYANT
JOHN CETRULE
T. G. CRAWFORD
†R. C. DEALE
U. S. EBERHARDT
S. A. EINSTEIN
R. F. GAGG
W. W. GILBERT
J. J. HARMAN
†R. E. W. HARRISON
F. V. HARTMAN
F. O. HOAGLAND
H. J. HOLTZCLAW
R. T. KENT
H. J. KURTZ
A. H. LYON
M. J. REED
F. C. SPENCER
C. C. STEVENS
J. S. TAWRESEY
C. H. WHITAKER
ERNEST WOOLER

SUBCOMMITTEE CHAIRMEN

No. 1 on Surfaces Produced by Tools and Abrasives, JOHN CETRULE
No. 2 on Surfaces Produced by Molds, Dies, Rolls, or Any Other Means of Deforming Materials

CLASSIFICATION AND DESIGNATION OF SURFACE QUALITIES (B-46) *(continued)*

No. 3 on Coated Surfaces, G. B. Hogaboom
No. 4 on Symbols for Indicating Surface Quality on Drawings, T. G. Crawford
No. 5 on Ways, Means, and Apparatus for Measuring Quality of Surface, J. R. Weaver
No. 6 on Finance, R. E. W. Harrison

COMBUSTION SPACE FOR SOLID FUELS (B-50)

**Sole sponsorship. Sectional Committee organized June, 1933*

A.S.M.E. Members (Total personnel, 21)

C. E. Bronson, *Chairman*
W. G. Christy
John Hunter
A. J. Johnson
†V. G. Leach
T. A. Marsh
J. F. McIntire
R. H. Rowland
†John Van Brunt

Subcommittee Chairmen

No. 1 on Purpose and Scope, C. E. Bronson
No. 2 on Combustion and Design, B. M. Guthrie
No. 3 on Warm Air Furnaces, J. H. Manny
No. 4 on Steel Heating Boilers, W. B. Russell
No. 5 on Cast Iron Boilers, J. F. McIntire

SCHEME FOR IDENTIFICATION OF PIPING SYSTEMS (A-13)

**Joint sponsorship with the National Safety Council. Sectional Committee organized June, 1922*

A.S.M.E. Members (Total personnel, 36)

E. E. Ashley
W. L. Bunker
Crosby Field
E. L. Hopping
H. L. Miner
H. S. Smith
Frank Thornton

Subcommittee Chairmen

Identification by Colors
Classification, Crosby Field
Identification Markings Other Than Color, W. S. Morrison

MINIMUM REQUIREMENTS FOR PLUMBING AND STANDARDIZATION OF PLUMBING EQUIPMENT (A-40)

**Joint sponsorship with the American Society of Sanitary Engineering. Sectional Committee organized August, 1928*

A.S.M.E. Members (Total personnel, 46)

J. J. Crotty
J. F. Carney
A. M. Houser
G. W. Martin
(A. H. Morgan, *Alternate*)
†W. R. Webster

Subcommittee Chairmen

No. 1 on Minimum Requirements for Plumbing, W. C. Groeniger
No. 2 on Staple Vitreous China Plumbing Fixtures, E. S. Aitkin
No. 3 on Staple Porcelain (All Clay) Plumbing Equipment, E. S. Aitkin
No. 4 on Enameled Sanitary Ware, A. H. Cline, Jr.
No. 5 on Traps, A. R. McGonegal
No. 6 on Brass Plumbing Products, J. L. Murphy
No. 7 on Brass Fittings for Flared Copper Tubes, F. L. Riggin
No. 8 on Cast Iron Soil Pipe and Fittings, J. J. Crotty
No. 9 on Gasoline, Oil, and Grease Separators, J. J. Crotty
No. 11 on Soldered Fittings for Tubing, A. M. Houser
No. 12 on Minimum Air Gaps in Plumbing Systems, W. K. McAfee

ELECTRIC MOTOR FRAME DIMENSIONS (C-28)

**Joint Sponsorship with the National Electrical Manufacturers Association. Sectional Committee organized November, 1927*

A.S.M.E. Members (Total personnel, 31)

C. A. Adams
S. A. Einstein
E. W. Ely
F. S. English
W. F. Jones
P. G. Rhoads
†A. G. Trumbull

ROLLED THREADS FOR SCREW SHELLS OF ELECTRIC SOCKETS AND LAMP BASES (C-44)

**Joint sponsorship with the National Electrical Manufacturers Association. Sectional Committee organized March, 1929*

A.S.M.E. Members (Total personnel, 17)

†E. J. Bryant
†Earle Buckingham
A. B. Morgan
†E. S. Sanderson

LETTER SYMBOLS AND ABBREVIATIONS FOR SCIENCE AND ENGINEERING (Z-10)

**Joint sponsorship with the American Association for the Advancement of Science, American Institute of Electrical Engineers, American Society of Civil Engineers, and the Society for the Promotion of Engineering Education. Sectional Committee organized January, 1926. Reorganized October, 1935*

A.S.M.E. Members (Total personnel, 37)

†S. A. Moss, *Vice-Chairman*
R. M. Anderson
(E. P. Warner, *Alternate*)
K. H. Condit
†R. J. S. Pigott
(†S. R. Beitler, *Alternate*)
Frank Thornton, Jr

Subcommittee Chairmen

No. 1 on Letter Symbols and Signs for Mathematics, A. A. Bennett
No. 2 on Symbols for Hydraulics, J. C. Stevens
No. 3 on Symbols for Mechanics, R. E. Peterson
No. 4 on Symbols for Structural Analysis, Albert Haertlein
No. 5 on Symbols for Heat and Thermodynamics, S. A. Moss
No. 6 on Symbols for Photometry, E. C. Crittenden
No. 7 on Aeronautical Symbols
No. 8 on Symbols for Electric and Magnetic Quantities, J. F. Meyer
No. 9 on Symbols for Radio, H. M. Turner
No. 10 on Symbols for Physics, H. K. Hughes
No. 11 on Abbreviations for Engineering and Scientific Terms, G. A. Stetson

DRAWINGS AND DRAFTING ROOM PRACTICE (Z-14)

**Joint sponsorship with the Society for the Promotion of Engineering Education. Sectional Committee organized July, 1926*

A.S.M.E. Members (Total personnel, 53)

F. DeR. Furman, *Chairman*
C. W. Keuffel, *Secretary*
T. G. Crawford
H. P. Frear
T. E. French
A. C. Harper
E. R. Hill
A. M. Houser
Alfred Iddles
†Samuel Ketchum
F. R. Laney
H. B. Langille
Rudolph Michel
F. W. Ming
W. C. Mueller
E. B. Neil
J. W. Owens
F. C. Panuska
†E. S. Smith

Subcommittee Chairmen

No. 1 on Specifications for Paper and Cloth
No. 2 on Method of Indicating Dimensions
No. 3 on Lettering, T. G. Crawford

Power Test Codes Technical Committees

Article B6A, Par. 27: The Standing Committee on Power Test Codes shall, under the direction of the Council, have supervision of all the activities of the Society in connection with the A.S.M.E. Power Test Codes, including the interpretation of such codes.

The first Standing Committee on Power Test Codes was organized in December, 1918, to revise and extend the Power Test Codes which had been formulated by various technical committees appointed to develop particular codes. This work began in 1886.

STANDING COMMITTEE

Francis Hodgkinson, *Chairman and Representative on the Council* (1939)

A. G. Christie, *Vice-Chairman*

John Allhusen, *Junior Observer* (1939)

Term expires 1939	*Term expires 1940*

The Woman's Auxiliary to the A.S.M.E.

The Woman's Auxiliary to the A.S.M.E. was organized on May 10, 1923, and its Constitution and By-Laws was approved by the Council of the A.S.M.E. on October 27, 1924. The objects of the Auxiliary are to render service to all that pertains to the interest of the profession of mechanical engineering; to cooperate with any committees of the A.S.M.E.; and to assist the sons and daughters of the members of the Society or worthy students of mechanical engineering in obtaining scholarships; and to promote any other objects consistent with the aims or objects of the A.S.M.E.

OFFICERS

President, MRS. GEORGE W. FARNY
First Vice-President, MRS. JOHN H. R. ARMS
Second Vice-President, MRS. E. C. STAHL
Third Vice-President, MRS. RANDALL B. PURDY
Fourth Vice-President, MRS. COLEMAN SELLERS, 3D
Fifth Vice-President, MRS. HARRY A. SCHWARTZ
Recording Secretary, MRS. CHARLES E. GUS
Corresponding Secretary, MRS. PHILIP E. FRANK
Treasurer, MRS. A. H. MORGAN

STANDING COMMITTEE CHAIRMEN

Education, MRS. ROY V. WRIGHT
Ways and Means, MRS. FREDERICK M. GIBSON
Program, MRS. C. B. LEPAGE
Membership, MRS. RANDALL B. PURDY
Courtesy, MRS. CYRIL G. HUMPHREYS
Hospitality, MRS. JAMES T. McQUEENEY
Publicity, MISS BURTIE HAAR
Custodian, MISS BURTIE HAAR

COUNCIL REPRESENTATIVES

R. F. GAGG
J. H. HERRON

Awards

The following paragraphs deal with the medals, awards, scholarships, and loan funds which come within the jurisdiction of the A.S.M.E. Other awards available to Student Members are listed in *Mechanical Engineering*, February, 1938, page 183. The Society also participates with other engineering societies in a number of joint awards. Further details concerning all the awards will be found in a series of articles beginning in the October, 1938, issue of *Mechanical Engineering*.

Honorary Membership, to which persons of acknowledged professional eminence are elected by unanimous vote of Council under the provisions of the By-Laws and Rules. A list of honorary members is given on page RI-41.

Life Membership, which may be conferred by the Council for distinguished service to the Society; or secured by a member by payment for an annuity in accordance with the provisions of the By-Laws.

A.S.M.E. Medal, established by the Society in 1920 to be presented, together with an engraved certificate, for distinguished service in engineering and science. May be awarded for general service in science having possible application in engineering.

Holley Medal, instituted and endowed in 1924 by George I. Rockwood, Past Vice-President of the Society, to be bestowed, together with an engraved certificate, for some great and unique act of genius of engineering nature that has accomplished a great and timely public benefit.

Worcester Reed Warner Medal, provision for which was made in the will of Worcester Reed Warner, Honorary Member of the Society, is a gold medal to be bestowed, together with an engraved certificate, on the author of the most worthy paper received, dealing with progressive ideas in mechanical engineering or efficiency in management.

Melville Medal, established in 1914 by the bequest of Rear-Admiral George W. Melville, Honorary Member and Past-President of the Society, to be presented, together with an engraved certificate, for an original paper or thesis of exceptional merit, presented to the Society for discussion and publication, to encourage excellence in papers. The medal may be presented annually.

Spirit of St. Louis Medal, established by an endowment fund created in 1929 by citizens of St. Louis, Mo., to be awarded for meritorious service in the advancement of aeronautics. This medal will be awarded at the discretion of the Council of the Society at approximately three-year periods upon the recommendation of its Board of Honors and Awards.

Junior Award, annual cash award of $50, estabished in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with an engraved certificate, for the best paper or thesis submitted by a Junior Member.

Student Awards, two annual cash awards of $25 each, established in 1914, from a fund created by Henry Hess, Past Vice-President of the Society, to be presented, together with engraved certificates, for the best papers or theses submitted by Student Members. The awards for 1932 and subsequent years have been given, one for undergraduate and the other for postgraduate work.

Charles T. Main Award, annual cash award of $150, established in 1919 from a fund created by Charles T. Main, Past-President of the Society, to be awarded, together with an engraved certificate, to a Student Member of the Society, for the best paper within the general subject of the influence of the profession upon public life. The exact subject is assigned by the Board of Honors and Awards, subject to the approval of the Council, and is announced each year through the Honorary Chairman of the Student Branches.

SCHOLARSHIPS AND LOAN FUNDS

Max Toltz: Loan Fund of $15,000 established by Major Max Toltz, former member of the Council of the Society, the income to be used for assistance to Student Members.

John R. Freeman: Fund of $25,000 established in 1926 by John R. Freeman, Past-President of the Society, the income to be used for travel scholarships and research.

Woman's Auxiliary: Scholarship or Fellowship offered by the Woman's Auxiliary to the Society to assist sons and daughters of members or worthy students of mechanical engineering.

RECIPIENTS OF AWARDS

The names of the recipients of the different awards to date are given in the following lists, together with the dates of presentation, and the services or papers for which the awards were made. There were no awards for the years not listed.

A.S.M.E. Medal

1921 Hjalmar Gotfried Carlson, in recognition of the services rendered the Government because of his invention and part in the production of 20,000,000 Mark III drawn steel booster casings used principally as a component of 75-mm high-explosive shells, but also used extensively in gas shells and bombs

1922 Frederick Arthur Halsey, for his paper describing the premium system of wage payments presented before the Society at the Providence Meeting in 1891, as the adoption of the methods there proposed has had a profound effect toward harmonizing the relations of worker and employer

1923 John Ripley Freeman, for his eminent service in engineering and manufacturing by his meritorious work in fire prevention and the preservation of property

1926 R. A. Millikan, in recognition of his contributions to science and engineering

1927 Wilfred Lewis, for his contributions to the design and construction of gear teeth

1928 Julian Kennedy, for his services and contributions to the iron and steel industry

1929 William LeRoy Emmet, for his contributions in the development of the steam turbine, electric propulsion of ships, and other power-generating apparatus

1931 Albert Kingsbury, for his research and development work in the field of lubrication

1933 Ambrose Swasey, for his contributions to the advancement of the engineering profession and for his part in the development of the turret lathe and the astronomical telescope

1934 Willis H. Carrier, in recognition of his research and development work in air-conditioning

1935 Charles T. Main, for distinguished achievements in the textile and other industries, in engineering education, and for eminent service to the engineering profession

1936 Edward Bausch, for meritorious mechanical developments in the field of optics

1937 Edward P. Bullard, for outstanding leadership in the development of station-type machine tools

1938 Stephen J. Pigott, for outstanding leadership in marine propulsion and construction.

Holley Medal

1924 Hjalmar Gotfried Carlson, for his inventions and processes which made possible the timely production of drawn steel booster casings for artillery ammunition, thereby aiding victory in the World War (diploma in recognition of achievements presented in 1921)

1927 Elmer Ambrose Sperry, for achievements and inventions that have advanced the naval arts, including the gyroscope that has freed navigation from the dangers of the fluctuating magnetic compass

1929 Baron Chuzaburo Shiba, for his contributions to knowledge through fundamental research, including the field of aerodynamics, by the development of ultra-rapid kinematographic methods

1934 Irving Langmuir, for his contributions to science and engineering, including the development of gas-filled incandescent lamps, thoriated filament for thermionic emission, atomic hydrogen welding, phase control operation of the thyratron tube, and fundamental research in oil films

1936 Henry Ford, for revolutionary influence through invention and practice on transportation and on mass production methods in manufacturing

1937 Frederick G. Cottrell, for preeminent public service—the invention of electric precipitation—advancement of the science of gas liquefaction—gifts for engineering research

1938 Francis Hodgkinson, for meritorious services in the development of the steam turbine.

Worcester Reed Warner Medal

1933 Dexter S. Kimball, for his contributions to efficiency in management as exemplified by his recently revised "Principles of Industrial Organization" and by his many articles, engineering society papers, and public addresses
1934 Ralph E. Flanders, for his contributions to a better understanding of the relationship of the engineer to economic problems and social trends as exemplified by the many papers which he has presented
1935 Stephen Timoshenko, for his contributions to the theory of the design of elastic structures and the treatment of dynamics of moving machinery
1936 Charles M. Allen, for his early and continued hydraulic laboratory work and for the permanent value of the papers on his development of methods of testing large hydraulic turbine installations
1937 Clarence F. Hirshfeld, for his research and contributions to the theory and practice of heat-power engineering as exemplified by books and papers
1938 Lawford H. Fry, for contributions relating to improved locomotive boiler design and utilization of better materials in railway equipment.

Melville Medal

1927 Leon P. Alford, "Laws of Manufacturing Management"
1929 Joseph W. Roe, "Principles of Jig and Fixture Practice"
1930 Herman Diederichs and William D. Pomeroy, "The Occurrence and Elimination of Surge or Oscillating Pressure in Discharge Lines From Reciprocating Pumps"
1931 Arthur E. Grunert, "Comparative Performance of a Pulverized-Coal-Fired Boiler Using Bin System and Unit System of Firing"
1932 Alexey J. Stepanoff, "Leakage Loss and Axial Thrust in Centrifugal Pumps"
1933 William E. Caldwell, "Characteristics of Large Hell Gate Direct-Fired Boiler Units"
1935 Oscar R. Wikander, "Draft-Gear Action in Long Trains"
1936 H. A. Stevens Howarth, "The Loading and Friction of Thrust and Journal Bearings With Perfect Lubrication"
1937 Alfred J. Büchi, "Supercharging of Internal-Combustion Engines With Blowers Driven by Exhaust-Gas Turbines"
1938 Alphonse I. Lipetz, "Air Resistance of Railroad Equipment."

Spirit of Saint Louis Medal

1929 Daniel Guggenheim, founder of the Guggenheim Fund for the Promotion of Aeronautics
1932 Paul Litchfield, for his work in encouraging and sponsoring airship design and construction in this country
1935 Will Rogers, for his splendid, constructive, and unselfish work in the achievement of aviation, and the building up of public confidence in aviation through his articles in the press, over the radio, and from the speaker's platform
1938 James H. Doolittle, for meritorious service in the advancement of aeronautics.

Junior Award

1915 Ernest O. Hickstein, "Flow of Air Through Thin Plate Orifices"
1916 L. M. McMillan, "The Heat Insulating Properties of Commercial Steam-Pipe Coverings"
1919 E. D. Whalen, "Properties of Airplane Fabrics"
1921 S. Logan Kerr, "Moody Ejector Turbine"
1922 R. H. Heilman, "Heat Losses From Bare and Covered Wrought-Iron Pipe at Temperatures up to 800 Degrees Fahrenheit"
F. L. Kallam, "Preliminary Report on the Investigation of the Thermal Conductivity of Liquids"
1923 S. S. Sanford and S. Crocker, "The Elasticity of Pipe Bends"
1924 R. H. Heilman, "Heat Losses Through Insulating Material"
1925 Gilbert S. Schaller, "An Investigation of Seattle as a Location for a Synthetic Foundry Industry"
1927 William M. Frame, "Stresses Occurring in the Walls of an Elliptical Tank Subjected to Low Internal Pressure"
1928 M. D. Aisenstein, "A New Method of Separating the Hydraulic Losses in a Centrifugal Pump"
1929 Arthur M. Wahl, "Stresses in Heavy, Closely Coiled Helical Springs"
1930 Ed Sinclair Smith, "Quantity-Rate Fluid Meters"
1931 M. K. Drewry, "Radiant-Superheater Developments"
1932 Edmond M. Wagner, "Frictional Resistance of a Cylinder Rotating in a Viscous Fluid Within a Coaxial Cylinder"
1933 Townsend Tinker, "Surface Condenser Design and Operating Characteristics"
1934 John I. Yellott, Jr., "Supersaturated Steam"
1935 Stanley J. Mikina, "Effect of Skewing and Pole Spacing on Magnetic Noise in Electrical Machinery"
1936 Harwood F. Mullikan, Jr., "Evaluation of Effective Radiant Heating Surface and Application of the Stefan-Boltzman Law to Heat Absorption in Boiler Furnaces"
1937 Leslie J. Hooper, "American Hydraulic-Laboratory Practice"
1938 Arthur C. Stern, "Separation and Emission of Cinders and Fly Ash."

Student Award

1916 Boynton M. Green, Stanford University, "Bearing Lubrication"
Howard E. Stevens, Rensselaer Polytechnic Institute, "An Investigation of the Dynamic Pressure on Submerged Flat Plates"
M. Adam, Louisiana State University, "The Adaptability of the Internal Combustion Engine to Sugar Factories and Estates"
1917 H. R. Hammond and C. W. Holmberg, The Pennsylvania State College, "Study of Surface Resistance With Glass as the Transmission Medium"
1919 C. F. Leh and F. G. Hampton, Stanford University, "An Experimental Investigation of Steel Belting"
W. E. Helmick, Stanford University, "An Experimental Investigation of Steel Belting"
1920 Howard G. Allen, Cornell University, "Wire Stitching Through Paper"
1921 Karl H. White, University of Kansas, "Forces in Rotary Motors"
Richard H. Morris and Albert J. R. Houston, University of California, "A Report Upon an Investigation of the Herschel Type of Improved Weir"
1923 Charles F. Olmstead, University of Minnesota, "Oil Burning for Domestic Heating"
H. E. Doolittle, University of California, "The Integrating Gate: A Device for Gaging in Open Channels"
1924 George Stuart Clark, Stanford University, "Two Methods Used for the Determination of the Gasoline Content of Absorption Oils in Absorption Plants"
L. J. Franklin and Charles H. Smith, Stanford University, "The Effect of Inaccuracy of Spacing on the Strength of Gear Teeth"
1925 Harry Pease Cox, Jr., Rensselaer Polytechnic Institute, "A Study of the Effect of End Shape on the Towing Resistance of a Barge Model"
W. S. Montgomery, Jr., and E. Ray Enders, Jr., Pennsylvania State College, "Some Attempts to Measure the Drawing Properties of Metals"
1926 R. E. Peterson, University of Illinois, "An Investigation of Stress Concentration by Means of Plaster of Paris Specimens"
Cecil G. Heard, University of Toronto, "Pressure Distribution Over U.S.A. 27 Aerofoil With Square Wing Tips—Model Tests"
1927 Alfred H. Marshall, Princeton University, "Evaporative Cooling"
Roger Irmin Eby, University of Washington, "Measurement of the Angular Displacement of Flywheels"
1928 Clarence C. Franck, Johns Hopkins University, "Condition Curves and Reheat Factors for Steam Turbines"
1929 Frank Vernon Bistrom, University of Washington, "An Investigation of a Rotary Pump"
William Wallace White, University of Washington, "An Investigation of a Rotary Pump"
1930 Gerard Eden Claussen, Polytechnic Institute of Brooklyn, "High-Temperature Oxidation of Steel"
Harold L. Adams and Richard L. Stith, University of Washington, "A Wind Tunnel for Undergraduate Laboratory Experiments"
1931 Jules Podnossoff, Polytechnic Institute of Brooklyn, "Pressure and Energy Distribution in Multi-Stage Steam Turbines Operating Under Varying Conditions"
1932 H. E. Foster, Jr., University of Tennessee, "Factors Affecting Spray Pond Design" (Undergraduate Award)
William A. Mason, Stanford University, "An Experimental Investigation of the Flame Propagation in Internal-Combustion Engines" (Postgraduate Award)

1933 HUGO V. CORDIANO, Polytechnic Institute of Brooklyn, "Thermal Analysis of Lithium–Magnesium System of Alloys" (Undergraduate Award)
JAMES A. OSTRAND, JR., Princeton University, "Sudden Enlargement in the Open Channel" (Postgraduate Award)

1934 H. REYNOLDS HUDSON, Georgia School of Technology, "Dynamic Balance and Functional Utility Applied to Automotive Design" (Undergraduate Award)

1935 CHARLES P. BACHA, Rutgers University, "The Behavior of Metals Subjected to Combined Stress" (Postgraduate Award)
ROBERT W. BEAL, Oregon State College, "Do Lubricating Oils Wear Out?" (Undergraduate Award)

1936 LEON B. STINSON, Oklahoma Agricultural and Mechanical College, "Polymerized Motor Fuels; Their Economic Significance" (Undergraduate Award)
DEWITT D. BARLOW, JR., Princeton University, "The Critical Speeds of Lateral Vibrations of Shafts With Gyroscopic Effects" (Postgraduate Award)

1937 GINO J. MARINELLI, Rensselaer Polytechnic Institute, "Investigation of the Towing Resistance of a Model Submarine Hull" (Undergraduate Award)

1938 MARSHALL C. LONG, Princeton University, "An Investigation Into the Angular Characteristics of an Adjustable Blade Current Meter" (Postgraduate Award)
DONALD C. MCSORLEY, Michigan State College, "Humidity Insulation" (Undergraduate Award).

CHARLES T. MAIN AWARD

1925 CLEMENT R. BROWN, Catholic University of America. Subject: "The Influence of the Locomotive on the Unity of the United States"

1926 W. C. SAYLOR, Johns Hopkins University. Subject: "The Effect of the Cotton Gin Upon the History of the United States During Its First Seventy Years"

1927 No Award. Subject: "Scientific Management and Its Effect Upon the Industries"

1928 ROBERT M. MEYER, Newark College of Engineering. Subject: "Scientific Management and Its Effect Upon Manufacturing"

1929 No award. Subject: "The Influence of Engineering on Farm Production"

1930 JULES PODNOSSOFF, Polytechnic Institute of Brooklyn. Subject: "The Value of the Safety Movement in the Industries"

1931 ROBERT E. KLISE, University of Michigan. Subject: "Interchangeability—Its Development and Significance in Industry"

1932 MARSHALL ANDERSON, University of Michigan. Subject: "Apprenticeship and Vocational Training"

1933 GEORGE D. WILKINSON, JR., Newark College of Engineering. Subject: "Progress in the Prevention of Smoke and Atmospheric Pollution"

1934 PHILIP P. SELF, Colorado State College, "Air Conditioning—Its Practicability and Relation to Public Welfare"

1935 G. LOWELL WILLIAMS, Lafayette College. Subject: "Coordinated Transportation—An Economic Comparison of Railroad, Bus, Truck, Water, and Air Transportation for Long and Short Haul"

1936 No award. Subject: "Development in the Generation and Distribution of Power and Their Effect Upon the Consumer"

1937 ALLAN P. STERN, Case School of Applied Science. Subject: "The Influence of the Introduction of Labor Saving Machinery Upon Employment in the United States"

1938 EDWARD W. CONNOLLY, University of Detroit. Subject: "Economic Limitations in Engineering Design, With Concrete Examples."

FREEMAN TRAVEL SCHOLARSHIP

1927 HERBERT N. EATON
1928 BLAKE R. VAN LEER
1929 ROBERT T. KNAPP
1931 REGINALD WHITAKER
1932 G. ROSS LORD
1933, 1934 H. J. CASEY
1935, 1936 VICTOR L. STREETER

Honorary Members

HONORARY MEMBERS IN PERPETUITY

ALEXANDER LYMAN HOLLEY, Founder of the Society. Died 1882.

JOHN EDSON SWEET, Founder of the Society. Died 1916.

HENRY ROSSITER WORTHINGTON, Founder of the Society. Died 1880.

DECEASED HONORARY MEMBERS

	ELECTED	DIED
HORATIO ALLEN	1880	1889
SIR WILLIAM ARROL	1905	1913
SIR JOHN AUDLEY FREDERICK ASPINALL	1911	1937
WILLIAM WALLACE ATTERBURY	1925	1935
SIR BENJAMIN BAKER	1886	1907
JOHANN BAUSCHINGER	1884	1893
SIR HENRY BESSEMER	1891	1898
SIR FREDERICK JOSEPH BRAMWELL	1884	1903
JOHN ALFRED BRASHEAR	1908	1920
GUSTAVE CANET	1900	1908
ANDREW CARNEGIE	1907	1919
DANIEL KINNEAR CLARK	1882	1896
RUDOLPH JULIUS EMMANUEL CLAUSIUS	1882	1888
SIR JOHN GOODE	1889	1892
PETER COOPER	1882	1883
CHARLES DE FRÉMINVILLE	1919	1936
CARL GUSTAF PATRICK DE LAVAL	1912	1913
RUDOLPH DIESEL	1912	1913
JAMES DREDGE	1886	1906
VICTOR DWELSHAUVERS-DERY	1886	1913
THOMAS ALVA EDISON	1904	1931
ALEXANDRE GUSTAVE EIFFEL	1889	1923
MARSHAL FERDINAND FOCH	1921	1929
SIR CHARLES DOUGLAS FOX	1900	1921
JOHN RIPLEY FREEMAN	1932	1932

MASAWO KAMO	1929
GEORGE A. ORROK	1936
GRANDE UFFICIALE ING. PIO PERRONE	1920
CHARLES M. SCHWAB	1918
WILLIAM H. TSCHAPPAT	1938
SAMUEL MATTHEWS VAUCLAIN	1920
RIGHT HONORABLE LORD WEIR	1920
ORVILLE WRIGHT	1918

Past-Presidents

A list of past vice-presidents, managers, treasurers, and secretaries will be found in the 1930 Record and Index, pages 10–12. Dates in parentheses denote year of death.

ALEXANDER LYMAN HOLLEY, *Chairman of the Preliminary Meeting for Organization of The American Society of Mechanical Engineers* (1882)

1880–1882 ROBERT HENRY THURSTON (1903)
1883 ERASMUS DARWIN LEAVITT (1916)
1884 JOHN EDSON SWEET (1916)
1885 JOSEPHUS FLAVIUS HOLLOWAY (1896)
1886 COLEMAN SELLERS (1907)
1887 GEORGE H. BABCOCK (1893)
1888 HORACE SEE (1909)
1889 HENRY ROBINSON TOWNE (1924)
1890 OBERLIN SMITH (1926)
1891 ROBERT WOOLSTON HUNT (1923)
1892 CHARLES HARDING LORING (1907)
1893–1894 ECKLEY BRINTON COXE (1895)
1895 EDWARD F. C. DAVIS (1895)
1895 CHARLES ETHAN BILLINGS (1920)
1896 JOHN FRITZ (1913)
1897 WORCESTER REED WARNER (1929)
1898 CHARLES WALLACE HUNT (1911)
1899 GEORGE WALLACE MELVILLE (1912)
1900 CHARLES HILL MORGAN (1911)
1901 SAMUEL T. WELLMAN (1919)
1902 EDWIN REYNOLDS (1909)
1903 JAMES MAPES DODGE (1915)
1904 AMBROSE SWASEY (1937)
1905 JOHN RIPLEY FREEMAN (1932)
1906 FREDERICK WINSLOW TAYLOR (1915)
1907 FREDERICK REMSEN HUTTON (1918)
1908 MINARD LAFEVER HOLMAN (1925)
1909 JESSE MERRICK SMITH (1927)
1910 GEORGE WESTINGHOUSE (1914)
1911 EDWARD DANIEL MEIER (1914)
1912 ALEXANDER CROMBIE HUMPHREYS (1927)
1913 WILLIAM FREEMAN MYRICK GOSS (1928)
1914 JAMES HARTNESS (1934)
1915 JOHN ALFRED BRASHEAR (1920)
1916 DAVID SCHENCK JACOBUS
1917 IRA NELSON HOLLIS (1930)
1918 CHARLES THOMAS MAIN
1919 MORTIMER ELWYN COOLEY
1920 FRED J. MILLER
1921 EDWIN S. CARMAN
1922 DEXTER SIMPSON KIMBALL
1923 JOHN LYLE HARRINGTON
1924 FREDERICK ROLLINS LOW (1936)
1925 WILLIAM FREDERICK DURAND
1926 WILLIAM LAMONT ABBOTT
1927 CHARLES M. SCHWAB
1928 ALEX DOW
1929 ELMER AMBROSE SPERRY (1930)
1930 CHARLES PIEZ (1933)
1931 ROY V. WRIGHT
1932 CONRAD N. LAUER
1933 A. A. POTTER

Index to Society Records, Part I

The page numbers in this section are preceded by the letters "RI," which are omitted in the following index.

Abbreviations and Symbols, Graphical, Comm. 31
Abbreviations and Symbols, Letter, Comm. 30
Abrasive Wheels, Rep. on Safety Comm. 33
Acoustical Measurements, Reps. on Comm. 31
Administrative Comm. 7
Admissions Comm. 5
Advertising Manager, A.S.M.E. 5
Advisory Board on Professional Status. 7
Advisory Board on Technology 7
Aeronautic Div.
  Exec. Comm. 10
  General Comm. 10
  Reps. on Other Activities 10
Aeronautics, Rep. on Safety Comm. 33
Aims and Objectives, Comm. 7
Air Conditioning, Comm. 12
Aircraft Safety and Inspection, Rep. on Comm. 10, 33
Air Navigation, Obstructions, Rep. on Comm. 10, 31
Alfred Noble Prize, A.S.M.E. Rep. 9
Allowances and Tolerances, Gages, Comm. 26
American Association for the Advancement of Science, A.S.M.E. Reps. 8
American Engineering Council, A.S.M.E. Reps. 8
American Marine Standards, Rep. on Comm. 31
American Standards Association, A.S.M.E. Reps. 8
American Year Book Corporation, A.S.M.E. Rep. 8
Amusement Parks, Rep. on Safety Comm. 33
Applied Mechanics Div.
  Exec. Comm. 10
  Subcomms. 10
A.S.M.E. Medal
  Recipients 38
  Statement about 38
Assistant Secretaries, A.S.M.E. 5
Awards, A.S.M.E.
  Recipients 38
  Statements about 38
Awards Comm. *See* Honors and Awards Comm.
Ball and Roller Bearings, Comm. 26
Biography Advisory Comm. 7
Board of Review 7
Boiler Code
  Comm., Special 6, 36
  Conference Comm. 36
  Exec. Comm. 36
  Revision of Section VIII, Special Comm. 37
  Subcomms. 36
Boiler Feedwater Studies, Comm. 25
Boiler Furnace Refractories, Comm. 25
Boiler Furnaces, Radiant Heat, Comm. 25
Boilers, Rules for Inspection of, Comm. 36
Boilers, Special Design of, Comm. 36
Bolted Flanged Connections, Rules for, Comm. 37
Bolt, Nut, and Rivet Proportions, Comm. 28
Building Code for Light and Ventilation, Rep. on Comm. 31
Cast Iron Pipe, Reps. on Comm. 32
Cavitation, Comm. 11
Center for Safety Education, A.S.M.E. Rep. 8
Certificate and Pin, Fellow Grade, Comm. 7
Charles T. Main Award
  Recipients 40
  Statement about 38
Christie, Alexander G. 2, 3
Chucks and Chuck Jaws, Comm. 27
Citizenship Comm. 7
Coal, Classification of, Rep. on Comm. 31
Coal, Clean Bituminous, Rep. on Comm. 32
Coal Friability, Comm. 10
Coal-Handling Equipment, Rep. on Comm. 31
Coal Mines, Drainage, Rep. on Comm. 31
Colleges, Relations With, Comm. 6, 22
Compressed Air, Work in, Rep. on Safety Comm. 34
Compressed Air Machinery and Equipment, Safety Comm. 32
Compressors and Blowers
  Centrifugal and Turbo, Comm. 34
  Displacement, Comm. 35
Comptroller, A.S.M.E. 5
Condensers, Water Heating, and Cooling Equipment, Comm. 35
Condenser Tubes, Comm. 25
Constitution and By-Laws Comm. 6
Construction Work, Rep. on Safety Comm. 33
Containers for Gases and Liquids at Subzero Temperatures, Rules for, Comm. 37
Conveyors and Conveying Machinery, Safety Comm. 32
Coordinating Comm. (Corrosion), Rep. on. 25
Coordination Comm. (Heat Transfer) 11
Correlating Comm. A.S.A. Safety Code, Rep. on Comm. 33
Corrosion, Coordinating Comm., Rep. on. 25
Corrosion, Rep. on Comm. 26
Cottonseed Processing, Comm. 25
Council, A.S.M.E.
  Exec. Comm. 5
  Members of 5
  Special Comms. 7
Cranes, Derricks, and Hoists, Safety Comm. 33
Cut and Ground Thread Taps, Comm. 27
Cutting Metals, Comm. 12, 24
Cutting Tools, Single Point, Comm. 27
Daniel Guggenheim Medal Fund, Inc., A.S.M.E. Reps. 8, 10
Definitions and Values, Power Test Codes, Comm. 34
Depreciation Studies, Comm. 12
Displacement Pumps, Reciprocating Steam-Driven, Comm. 35
Drawings and Drafting Room Practice, Comm. 30
Drying, Comm. 12
Dues-Exempt Members' Contributions, Comm. 7
Dust Explosions, Reps. on Safety Comm. 33
Dust Separating Apparatus, Comm. 35
Economic Status of the Engineer Comm. 7
Edison Foundation, A.S.M.E. Rep. 8
Editor, A.S.M.E. 5
Education and Training for the Industries Comm. 6
Education, Comm. 7
Electrical Definitions, Rep. on Comm. 31
Electric Motor Frames, Comm. 30
Electric Sockets and Lamp Bases, Comm. 30
Electric Welding Apparatus, Rep. on Comm. 31
Elevators, Comm. 24
Elevators, Safety Code, Comm. 32
Engineering Foundation, A.S.M.E. Reps. 8
Engineering History Comm., A.S.M.E. Reps. 8
Engineering Registration, National Bur. of, A.S.M.E. Rep. 8
Engineering Societies, Cooperation in Safety Work, Rep. on Comm. 33
Engineering Societies Employment Service, A.S.M.E. Reps. 8
Engineers' Council for Professional Development, A.S.M.E. Reps. 8
Evaporating Apparatus, Comm. 35
Exhaust Systems, Rep. on Safety Comm. 33
Fans and Blowers, Comm. 12
Feedwater, Boiler Code Comm. 37
Feedwater Studies, Boiler, Comm. 25
Fellow Grade, Certificates and Pins, Comm. 7
Ferrous Materials, Comm. 36
Finance Comm. 5
Fire Tests, Building Construction and Materials, Rep. on Comm. 31
Floor and Wall Openings, Railings, and Toe Boards, Safety Comm. 33
Fluid Flow, Velocity Measurement of, Comm. 25
Fluid Meters, Comm. 24
Food Processing, Comm. 12
Forest Fire Protection, Rep. on Comm. 31
Forging and Hot Metal Stamping, Rep. on Safety Comm. 33
Foundry Equipment and Supplies, Comm. 29
Foundry Practice, Comm. 11
Freeman Fund, Comm. 7
Freeman Scholarships. *See* John R. Freeman Travel Scholarships
Fritz Medal Board of Award, A.S.M.E. Reps. 8
Fuel Oils, Reps. on Comm. 32
Fuels, Calorific Values, Rep. on Comm. 35
Fuels, Power Test Code Comm. 34
Fuels Div.
  Exec. Comm. 10
  Joint Meeting with A.I.M.E., Comm. 10
  Programs and Meetings, Comm. 10
Fuel Values, Joint Comm., A.S.M.E. Reps. 8, 10
Fusion Welding Requirements 37
Gages, Pressure and Vacuum, Comm. 29
Gantt Medal Board of Award, A.S.M.E. Reps. 8
Gas Mask Canisters, Rep. on Safety Comm. 33
Gas Producers, Comm. 35
Gear Lubricants, Rep. on Comm. 31
Gears, Comm. 28
Gear Teeth, Strength of, Comm. 24
George Westinghouse Bust Comm. 8
Glass, Safety, Rep. on Comm. 34
Graphic Arts Div., Exec. Comm. 11
Graphic Arts Forum, Comm. 11
Graphic Presentation Comm. 30
Guggenheim Medal Fund, A.S.M.E. Reps. 8, 10
Heating Boiler Code, Revision of, Comm. 37
Heating Boilers, Comm. 36
Heat Transfer Professional Group, Comm. 11
Holley Medal
  Recipients 38
  Statement about 38
Holmes Safety Association, A.S.M.E. Rep. 8
Honorary Members, List of 41
Honorary Membership, Statement about 38
Honors and Awards Comm. 6
Honors and Awards, Special Comm. of Board of 6
Hoover Medal Board of Award, A.S.M.E. Reps. 8
Hose Couplings, Screw Threads, Comm. 29
Hydraulic Div., Exec. Comm. 11
Hydraulic Prime Movers, Comm. 11, 35
Hydraulics, General, Comm. 11
Industrial Aerodynamics, Comm. 10
Industrial Instruments and Regulators, Comm. 12
Industrial Workers, Foundries, Protection of, Rep. on Safety Comm. 34
Industrial Workers, Protection of, Rep. on Safety Comm. 33
Industries, Education and Training for, Comm. 6
Instruments and Apparatus, Power Test Codes, Comm. 35
Internal-Combustion Engines, Comm. 35
International Electrotechnical Commission, A.S.M.E. Reps. 8
Iron and Steel Bars, Comm. 29
Iron and Steel Div., Exec. Comm. 11
Jig Bushings, Comm. 27
John Fritz Medal Board of Award, A.S.M.E. Reps. 8
John R. Freeman Travel Scholarships
  Recipients 40
  Statement about 38
Joseph A. Holmes Safety Association, A.S.M.E. Rep. 8
Journal of Applied Mechanics, Exec. Comm. 10
Junior Award
  Recipients 39
  Statement about 38
Ladders, Rep. on Safety Comm. 33
Laundry Machinery, Rep. on Safety Comm. 33
Leather Belting, Comm. 29
Library Comm. 6
Life Membership, Statement about 38
Lighting Factories, Mills, Rep. on Safety Comm. 33
Loading Platforms, Rep. on Comm. 31
Local Sections
  Exec. Comms. 14
  Nominating Comm. Groups of 7
  Regional Group Delegates to Annual Conferences 14
  Standing Comm. 6, 14
Locomotives, Boilers of, Comm. 36
Logging and Sawmill Machinery, Rep. on Safety Comm. 33
Low Voltage Electrical Hazard, Rep. on Safety Comm. 33
Lubrication, Comm. 24
Lubrication Engineering, Comm. 12
Machine Design, Comm. 11
Machine Pins, Comm. 29
Machinery, Speeds of, Comm. 31
Machine Shop Practice Div., Exec. Comm. 11
Machine Tapers, Comm. 27
Machine Tool Elements, Comm. 27
Machine Tools, Designations and Working Ranges, Comm. 27
Machining of Wood, Comm. 13
Main Award. *See* Charles T. Main Award
Management Div., Exec. Comm. 12
Management, Measures of, Comm. 25
Manhole Frames and Covers, Reps. on Comm. 31
Manual of Practice Comm. 7
Manual on Citizenship Comm. 7
Marston Award, A.S.M.E. Rep. 8
Materials Handling Div., Exec. Comm. 12
Materials, New, Boiler Code Comm. 37
Material Specifications, Comm. 36
Max Toltz Loan Fund, Statement about 38
Measures of Management, Comm. 25
Mechanical Power-Transmission Apparatus, Safety Comm. 32
Mechanical Refrigeration, Reps. on Safety Comm. 33
Mechanical Separation, Comm. 13
Mechanical Springs, Comm. 24
Medals, Comm. 6
Meetings and Program Comm. 5
Membership Comm. *See* Admissions Comm.
Melville Medal
  Recipients 39
  Statement about 38
Metallurgical Research, Rep. on Comm. 26
Metals, Cutting of, Comm. 12, 24
Metals, Effect of Temperature on, Comm. 24
Metals, Fatigue Phenomena of, Rep. on Comm. 26
Mid-Continent Office, Location of 5
Mid-West Office, Location of 5
Milling Cutters, Comm. 27
Miniature Boilers, Comm. 36
Model Smoke Law, Comm. 10

SOCIETY RECORDS—Part II

(Including Indexes to Publications)

[*Part I of Society Records for the year 1939 (containing Council and Committee Personnel and other general information) was issued as Section Two of the Transactions for February, 1939.*]

Depositories for A.S.M.E. Transactions in the United States RI-45

Depositories for A.S.M.E. Transactions Outside the United States RI-47

Indexes to A.S.M.E. Papers and Publications RI-49

- Regular Society Publications, 1939 . . . . . RI-49
- Special Publications Issued in 1939 . . . . . RI-49
- Miscellaneous Papers Presented at Meetings but not Published RI-49
- Publications Developed by the Technical Committees RI-49
- Biographies RI-51
- Books on Special Subjects RI-51

Index to *Mechanical Engineering*, 1939 . . . . . RI-53

Index to Transactions, 1939 . . . . . RI-63

JANUARY, 1940

VOL. 62, NO. 1

Transactions

of The American Society of Mechanical Engineers

Published on the tenth of every month, except March, June, September, and December

---

OFFICERS OF THE SOCIETY:

A. G. Christie, *President*

W. D. Ennis, *Treasurer* C. E. Davies, *Secretary*

COMMITTEE ON PUBLICATIONS:

C. B. Peck, *Chairman*

Coleman Sellers, 3d C. R. Soderberg

F. L. Bradley A. R. Stevenson, Jr.

George A. Stetson, *Editor*

ADVISORY MEMBERS OF THE COMMITTEE ON PUBLICATIONS:

W. L. Dudley, Seattle, Wash. A. N. Goddard, Detroit, Mich. E. J. Kates, New York, N. Y.

L. S. Marks, Cambridge, Mass. J. M. Todd, New Orleans, La. N. C. Ebaugh, Gainesville, Fla.

Junior Members

C. C. Kirby, New York, N. Y. H. B. Fernald, Jr., New York, N. Y.

Published monthly by The American Society of Mechanical Engineers. Publication office at 20th and Northampton Streets, Easton, Pa. The editorial department located at the headquarters of the Society, 29 West Thirty-Ninth Street, New York, N. Y. Cabel address, "Dynamic," New York. Price $1.50 a copy, $12.00 a year; to members and affiliates, $1.00 a copy, $7.50 a year. Changes of address must be received at Society headquarters two weeks before they are to be effective on the mailing list. Please send old as well as new address.... By-Law: The Society shall not be responsible for statements or opinions advanced in papers or .... printed in its publications (B13, Par. 4).... Entered as second-class matter March 2, 1928, at the Post Office at Easton, Pa. under the Act of August 24, 1912....

Copyrighted, 1940, by The American Society of Mechanical Engineers.

Depositories for A.S.M.E. Transactions in the United States

BOUND copies of the complete Transactions of The American Society of Mechanical Engineers will be found in the libraries in the United States and other countries which are listed on the following pages.

Indexes to A.S.M.E. Papers and Publications

THE following pages will serve as a guide to the current publications of the A.S.M.E. during the calendar year 1939, and also to publications developed by the technical committees. The publications of the Society are as follows:

REGULAR SOCIETY PUBLICATIONS, 1939

Mechanical Engineering, monthly (see index on pages RI-53-62)
A.S.M.E. Transactions, monthly (see index on pages RI-63-71)
Mechanical Catalog and Directory, 1940 edition

SPECIAL PUBLICATIONS ISSUED IN 1939

1938 Oil Engine Power Cost Report
1939 Proceedings of Oil and Gas Power Division
Manual on Cutting of Metals

Standards

Indicating Pressure and Vacuum Gages
Terminology and Definitions for Single Point Cutting Tools
Face-to-Face Dimensions of Ferrous Flanged and Welding End Valves
Malleable-Iron Screwed Fittings—150 Lb
Wrought-Iron and Wrought-Steel Pipe
Cast-Iron Pipe Flanges and Flanged Fittings, Class 125
Steel Pipe Flanges and Flanged Fittings for Maximum WSP of 150 to 2500 Lb

Power Test Codes

Displacement Compressors, Vacuum Pumps and Blowers
Instruments and Apparatus, Part 13—Speed Measurements

Research

Bibliography on Machining of Wood

Safety

Compressed-Air Machinery and Equipment

Papers Presented at A.S.M.E. Meetings, 1939

THE complete technical programs of the meetings of the Society and of its Professional Divisions have been published in *Mechanical Engineering* and may be located by consulting the index on pages RI-53-62. A considerable number of papers and reports included in these programs were not published during the year in either Transactions or *Mechanical Engineering*, but were issued in mimeographed or photo-offset form. Complete sets of these are on file for reference purposes at the office of the Society and the Engineering Societies Library, under the title of "Miscellaneous Papers Presented at A.S.M.E. Meetings, 1939." Photostatic copies of any of the papers may be secured from the Library at regular rates. A list of these papers and reports follows:

MISCELLANEOUS PAPERS PRESENTED AT A.S.M.E. MEETINGS IN 1939—NOT PUBLISHED

ANDERSON, A. W., Some Problems in the Burning of Fuel Oil
BERNHARD, R. K., PERRY, T. D., AND STERN, E. G., Super-Pressed Plywood
Bibliography on the Machining of Wood
BLISS, GEORGE F., Worsted System Spinning
BOELTER, L. M. K., Basic Engineering Factors in Agricultural Technology and Illustrations
BOSSE, L. J., Economic Status of Hardwood Dimension Industry
BRANDT, CARL D., Staple Rayon Spinning
COOK, D. D., Notes on Piston Rings and Cylinder Wear
DEGLER, HOWARD E., Interpretation of Smoky Exhaust of Diesel Engines
DODGE, J. M., Factors Which Influence the Design of Piston Rings and Materials Used in Them
DOST, F. J., Making Better Machine-Tool Castings
ELLIS, RAY E., Apprentice Training
FONDA, BAYARD P., Controlled Air Conditions in the Printing Industry
HEINZ, W. B., Performance Characteristics of Dye Jigs
HERBECK, C. J., Burning of Oathulls
KRONERT, JOSEF, Regulation of Power-Plant Variables
LLOYD, WILLIAM, Industrial Firing of Anthracite
MALEEV, V. L., Combustion-Chamber Development and Characteristics, as Applied to American High-Speed, Compression-Ignition Oil Engines
MAXWELL, C. R., AND ROSEN, C. G. A., The Development of the High-Speed Diesel Engine in the United States
MEDLEY, J. W., Development of Dimensional Control and Tolerances for Wood Products
NEFF, ELMER H., Apprenticeship in the Machine-Tool Industry
NEUMANN, G., AND WÜNSCH, G., Regulators
NIXON, STUART, Notes on Piston Rings From the Operator's Viewpoint
OVERBECK, J. E., AND BEITLER, S. R., Methods of Measuring Large Volumes of Natural Gas
PEARSON, HARRY R., Mountain Creek Steam Electric Station an Example of Semi-Outdoor Construction
Report on Oil-Engine Power Cost for 1938
RINCLIFFE, R. G., Modern Coal Purchasing
SCHMIDT, WALTER, Laws of Direct Regulation on a General Basis
SCOTT, DONALD C., Testing the Stiffness of Yarns and Twines
STEIN, THEODORE, Self-Regulation
Technical Memoranda on Automatic Control, 1938
TENOT, N. A., An Experimental Study of Regulation
VEIHMEYER, F. J., Water Regimen of Soils in Place in the Field
VINCENT, E. T., Injection Systems for Oil Engines
VOLZ, F. O., The Use of Electric Welded Construction for Columns and Bases in the Machine-Tool Industry
WEHMHOFF, B. L., Paper Testing
WILLIAMS, PAUL, Lubricating Systems for Diesel Engines
WORKMEN, T. R., Coordination of Fuel Engineering From the Mine to the Consumer

Publications Developed by the Technical Committees

THE Society's technical committees, the first of which was organized many years ago and all of which have been continuously at work on codes, standards, research, and other special reports, have developed a series of publications of permanent value to the membership. The following list is first presented here for record and for ready reference. This list covers the entire group of publications of these committees completed to date which are now available.

To assist the members in securing copies of these publications the sale price is also given. A discount of 10 per cent is allowed to A.S.M.E. members on standards and a 20 per cent discount on all other publications except where otherwise noted.

RESEARCH

Dynamic Loads on Gear Teeth (1932), $1.50
Fluid Meters:
Part 1—Theory and Application (1937), $3.00

Part 2—Description of Meters (1931), $1.75
Part 3—Selection and Installation (1933), $1.50
Report of the AGA-ASME Committee on Orifice Coefficients (1935), $2.75
Tests on Electrical Equipment for Drilling Rotary Drilled Oil Wells (1933), $0.85
Tests on Steam Equipment for Drilling Rotary Drilled Oil Wells (1932), $0.85
Roll-Neck Bearings (1935), $1.50
Bibliography on Cutting of Metals (1866–1930), $1.25
Bibliography on Deterioration of Condensing Equipment (1845–1930), $1.25
Bibliography on Effect of Temperature Upon Properties of Metals (1828–1931), $1.25
Bibliography on Management Literature and Supplement (1903–1935), $2.75
Bibliography on Mechanical Springs (1678–1927), $1.25
Bibliography on Woods of the World (1928), $1.25
Bibliography on Marketing Research (1935), $1.00

POWER TEST CODES

Test Codes for

Atmospheric Water-Cooling Equipment (1930), $0.45
Centrifugal and Rotary Pumps (revision in preparation)
Compressors and Exhausters (1935), $0.95
Displacement Compressors, Vacuum Pumps, and Blowers
Evaporating Apparatus (revision in preparation)
Feedwater Heaters (1927), $0.35
Gas Producers (1928), $0.55
Hydraulic Prime Movers (1938), $0.60
Internal-Combustion Engines (1930), $0.55
Liquid Fuels (1930), $0.35
Reciprocating Steam Engines (1935), $0.65
Reciprocating Steam-Driven Displacement Pumps (1927), $0.65
Refrigerating Systems (1927), $0.55
Solid Fuels (1931), $0.55
Speed-Responsive Governors (1927), $0.45
Stationary Steam-Generating Units (1936), $0.60
Steam Condensing Apparatus (1938), $0.65
Steam Locomotives (1927), $0.55
Steam Turbines (1928), $0.55

Supplementary Codes and Publications

Definitions and Values (1931), $0.40
General Instructions (1929), $0.35
Instruments and Apparatus:
Part 1—General Consideration (1935), $0.35
Part 2—Pressure Measurement; Chapter 1, Barometers, and Chapter 6, Tables, Multipliers, and Standards (revision in preparation)
Part 2—Pressure Measurement; Chapter 2, Static and Total Pressure, Static Holes and Tubes, Impact Tubes, and Chapter 3, Pipes for Pressure Measurements (1936), $0.65
Part 2—Pressure Measurement; Chapter 4, Bourdon, Bellows, Diaphragm, and Deadweight Gages (1938), $0.65
Part 3—Temperature Measurement; Chapter 1, General; Chapter 5, Pyrometric Cones; Chapter 6, Liquid-in-Glass Thermometers; and Chapter 7, Bourdon Tube Thermometers (1931), $0.75
Part 3—Temperature Measurement; Chapter 2, Radiation Pyrometers (1936), $0.55
Part 3—Temperature Measurement; Chapter 8, Optical Pyrometers (1933), $0.35
Part 4—Head Measuring Apparatus (1933), $0.35
Part 6—Electrical Measurements (1934), $1.25
Part 9—Heat of Combustion (1932), $0.40
Part 10—Flue and Exhaust Gas Analyses (1936), $1.35
Part 11—Determination of Quality of Steam (1931), $0.45
Part 12—Measurement of Time (1932), $0.35
Part 13—Speed Measurements (1939), $0.45
Part 14—Linear Measurements (1936), $0.55
Part 15—Measurement of Surface Areas (1937), $0.75
Part 16—Density Determinations (1931), $0.30
Part 17—Determination of the Viscosity of Liquids (1931), $0.45
Part 18—Humidity Determinations (1932), $0.50
Part 20—Smoke-Density Determinations (1936), $0.65
Part 21—Leakage Measurement, Chapter 1, Condenser Leakage Tests (1928), $0.35
Part 21—Leakage Measurement; Chapter 2, Boiler and Piping; Chapter 3, Steam Engine Leakage (1932), $0.35

BOILER CODE

Power Boiler Code (1937) Including Materials Specifications and 1938–1939 Addenda, $2.25
Locomotive Boiler Code (1937) with 1938–1939 Addenda, $0.55
Low-Pressure Heating Boiler Code (1935) with 1936–1938 Addenda, $0.65
Miniature Boiler Code (1937) with 1938–1939 Addenda, $0.50
Suggested Rules for Care of Power Boilers (1935), $0.70
A.S.M.E. Unfired Pressure Vessel Code (1937) with 1938–1939 Addenda, $0.75
A.S.M.E. Boiler Construction Code, Combined Edition (1937) with 1938–1939 Addenda, $5.50
Boiler Code Interpretation Sheets, $2.75 per set with binder. Single sheets, $0.15
Annual Subscription, $2.50

STANDARDS

Machine Shop Practice Standards

Shafting and Stock Keys (B17.1—1934), $0.45
Code for Design of Transmission Shafting (B17c—1927), $0.75
Woodruff Keys, Keyslots, and Cutters (B17f—1930), $0.35
Tolerances, Allowances, and Gages for Metal Fits (B4a—1925), $0.50
Screw Threads for Bolts, Nuts, Machine Screws, and Threaded Parts (B1.1—1935), $0.60
Wrench-Head Bolts and Nuts and Wrench Openings (B18.2—1933), $0.50
Slotted Head Proportions; Machine Screws, Cap Screws, and Wood Screws (B18c—1930), $0.45
Track Bolts and Nuts (B18d—1930), $0.40
Round Unslotted-Head Bolts, Carriage, Step, and Machine Bolts (revision in preparation)
Plow Bolts (B18f—1928), $0.35
Tinners', Coopers', and Belt Rivets (B18g—1928), $0.35
Rotating Air Cylinders and Adapters (B5.5—1932), $0.35
Jig Bushings (B5.6—1935), $0.35
T-Slots, Their Bolts, Nuts, Tongues, and Cutters (B5a—1927), $0.35
Tool Holder Shanks and Tool Post Openings (B5b—1929), $0.25
Milling Cutters (B5c—1930), $0.75
Taps—Cut and Ground Threads (revision in preparation)
Spur Gear Tooth Form (B6.1—1932), $0.45
Shaft Couplings (B49—1932), $0.35
Drawings and Drafting Room Practice (Z14.1—1935), $0.50
Small Rivets (B18a—1927), $0.30
Large Rivets: 1/2 In. Diameter and Larger (B18.4—1937), $0.65
Socket Set Screws and Socket Head Cap Screws (B18.3—1936), $0.40
Circular and Dovetail Forming Tool Blanks (B5.7—1936), $0.40
Chucks and Chuck Jaws (B5.8—1936), $0.45
Lathe Spindle Noses (B5.9—1936), $0.50
Machine Tapers (B5.10—1937), $0.50
Adjustable Adapters (B5.11—1937), $0.50
Fire Hose Coupling Screw Thread (B26—1925), $0.25
Hose Coupling Screw Threads (B33.1—1935), $0.25
Rolled Threads for Screw Shells of Electric Sockets and Lamp Bases (C44—1931), $0.35
Indicating Pressure and Vacuum Gages (B40—1939), $0.40
Terminology and Definitions for Single Point Cutting Tools (B5.13—1939), $0.40

Pipe and Fittings

Wrought-Iron and Wrought-Steel Pipe (B36.10—1939), $0.50
Code for Pressure Piping (no discount) (B31.1—1935), $1.00
Cast-Iron Pipe Flanges and Flanged Fittings for 25 Lb Maximum Saturated Steam Pressure (B16b2—1931), $0.40
Cast-Iron Pipe Flanges and Flanged Fittings for 125 Lb Maximum Saturated Steam Pressure (B16a—1939), $0.60
Cast-Iron Pipe Flanges and Flanged Fittings for 250 Lb Maximum Saturated Steam Pressure (B16b—1928), $0.50
Cast-Iron Pipe Flanges and Flanged Fittings for 800 Lb Maximum Hydraulic Pressure (B16b1—1931), $0.35
Face-to-Face Dimensions of Ferrous Flanged and Welding End Valves (B16.10—1939), $0.55
Malleable-Iron Screwed Fittings for 150 Lb Maximum Saturated Steam Pressure (B16c—1939), $0.50
Cast-Iron Screwed Fittings for 125 and 250 Lb Maximum Saturated Steam Pressure (B16d—1927), $0.35
Steel Pipe Flanges and Flanged Fittings for 150 to 2500 Lb Maximum Steam Service Pressure (B16e—1939), $1.25
Cast-Iron Long Turn Sprinkler Fittings for 150 and 250 Lb Maximum Saturated Steam Pressure (B16g—1929), and Addendum (B16g1—1937), $0.50

Scheme for the Identification of Piping Systems (A13—1928), $0.50
Cast-Iron Soil Pipe and Fittings (A40.1—1935), $0.65
Pipe Plugs (B16e2—1936), $0.35
Brass Fittings for Flared Copper Tubes (A40.2—1936), $0.35

Letter and Graphical Symbols

Symbols for Mechanics, Structural Engineering, and Testing Materials (Z10a—1932), $0.25
Symbols for Hydraulics (Z10b—1929), $0.35
Symbols for Heat and Thermodynamics (Z10c—1931), $0.30
Symbols for Photometry and Illumination (Z10d—1930), $0.20
Aeronautical Symbols (Z10e—1929), $0.35
Mathematical Symbols (Z10f—1928), $0.30
Letter Symbols for Electrical Quantities (Z10g1—1929), $0.20
Graphical Symbols for Electric Power and Wiring (Z10g2—1933), $0.20
Graphical Symbols for Radio (Z10g3—1933), $0.20
Graphical Symbols for Electrical Traction Including Railway Signaling (Z10g5—1933), $0.40
Graphical Symbols for Telephone and Telegraph Use (Z10g6—1929), $0.20
Symbols for Electrical Equipment of Buildings (C10—1924), $0.20
Abbreviations for Scientific and Engineering Terms (Z10i—1932), $0.40
Time Series Charts (Z15.2—1938), $1.25
Engineering and Scientific Charts for Lantern Slides (Z15.1—1932), $0.50
Graphical Symbols for Plumbing, Piping, Pipe Fittings, and Valves, Heating and Ventilating, Heat-Power Apparatus, Conventional Rivets, etc. (Z14.2—1935), $0.45

SAFETY

Safety Code for Elevators (A17.1—1937) (10 per cent discount), $1.00
Elevator Inspectors' Manual (A17.2—1937) (10 per cent discount), $0.75
Safety Code for Mechanical Power-Transmission Apparatus (10 per cent discount) (B15—1927), $0.35
Compressed-Air Machinery and Equipment (B19—1938), $0.30

JOINT CODE

API-ASME Code for Unfired Pressure Vessels for Petroleum Liquids and Gases (1938) (10 per cent discount), $1.00

Biographies

BIOGRAPHIES issued under the sponsorship of the A.S.M.E. Biography Advisory Committee are as follows:

Life of Henry Laurence Gantt, by L. P. Alford (1934), $5.00
Biography of John Stevens, by Archibald Douglas Turnbull (1928), $5.00
Autobiography of John A. Brashear (1924), $5.00
Biography of James Hartness, by Joseph W. Roe (1937), $4.00
Biography of Robert Henry Thurston, by William F. Durand (1929), $5.00
Biography of John Edson Sweet, by Dean A. W. Smith (1925), $4.50

Books on Special Subjects

Hydraulic Laboratory Practice (1929), $10.00
Bulletin 3, Munich Hydraulic Institute (1935), $3.75
Hydraulic Structures (1937), $18.00
1938 Oil Engine Power Cost Report (1939), $1.00
Creep Data (1938) (no discount), $12.00
General Discussion on Lubrication (1938) (no discount), $6.50
Corrosion-Resistant Metals (1936), $1.25
Manual on Cutting of Metals (1939), $5.00
1940 A.S.M.E. Mechanical Catalog and Directory, $3.00 (Sent gratis to members, upon request.)
Design Data on Strength of Materials (1938), $1.50
Theoretical Steam Rate Tables (1937), $1.25
Engineering's Part in the Development of Civilization (1939), $1.50
